SEC. 1346. Upon the order of the court fixing the time of hearing being made, the clerk shall place a certified copy of such order, which order shall contain the names of all the parties alleged in application to be interested in the matter, in the possession of the sheriff of the proper county, which shall be thereupon served upon each of the parties therein named in the same manner as a summons, and a return of the service shall be made and filed with the clerk within fourteen days after the delivery of said order to the sheriff, or if served by any other person, in cases where a summons could be served, then return shall be made within fourteen days after date of order. It shall be the duty of the clerk also to give public notice of such application and order, by publication in a newspaper, if any be printed and in circulation, in some county wherein such water district is situated, which notice shall be published at least once each week for two consecutive weeks, and which said notice shall contain the date of the filing of said motion, petition, or application, the name or names of the parties filing the same, a copy of the order made by the court for hearing, and shall notify all parties interested as owners in any ditch, canal, or reservoir on such stream or streams in such water district, as well as the persons named in the motion, petition, or application, to appear at said court or before the judge thereof, in vacation, at the time appointed and stated in the order, and that all persons interested as owners or consumers may then and there present his, her, or their proofs for or against any priority of right of water by appropriation sought to be shown by any party, by or through any ditch, canal, or reservoir (either as owner or consumer of water drawn therefrom), and in case any party mentioned in the motion, petition, or application can not be personally served in any county embraced in such water district, the published notice above provided shall be deemed sufficient service of notice: *Provided further*, That in addition to such publication the clerk shall mail such published notice to each party mentioned in the motion, petition, or application, directing the same to the address of such parties as stated in the sworn statement on file. Proof of the proper publication shall consist in the sworn certificate of the publisher of the paper in which notice is published, to which shall be attached a printed copy taken from such paper. [S. L. 1886, ch. 61, § 16.]

SEC. 1347. Any person or persons who shall knowingly and willfully cut, dig, or break down, or open any gate bank, embankment, or side of any ditch, canal, or reservoir, flume, tunnel, or feeder in which such person or persons may be joint owners, or on the property of another, or in the lawful possession of another or others, and used for the purpose of irrigation, milling, manufacturing, mining, or domestic purposes, with intent maliciously to injure any person, association, or corporation, or for his or her own gain, unlawfully, with the intention of stealing, taking, or causing to run, or pour out of such canal, or reservoir feeder, or flume, any water for his or her own profit, benefit, or advantage, to the injury of any other person, persons, association, or corporation lawfully in the use of such water, or of such ditch, canal, tunnel, feeder, or flume, he, she, it, or they, so offending, shall be deemed guilty of a misdemeanor, and, on conviction thereof, shall be fined in any sum not exceeding one hundred dollars, and may be imprisoned in the county jail not exceeding six months, or both, at the discretion of the court. [S. L. 1886, ch. 61, § 17.]

SEC. 1348. Any party or parties, representing any ditch, canal, or reservoir, or any number of parties, representing two or more ditches, canals, or reservoirs, which are affected, in common with each other, by any portion of the decree rendered by the district court, by which he, she, it, or they may feel aggrieved, may have an appeal from said district court to the supreme court, and in such case the party or parties joining, desiring an appeal, shall be the appellants, and the parties representing any one or more ditches, canals, or reservoirs affected in common, adversely to the interests of appellants, shall be appellees. The party or parties in such appeal shall, within sixty days after the date of the decree, file in the district court wherein any decree is entered under this chapter a notice of appeal in writing, stating that such party or parties appeals to the supreme court of the Territory from the decree rendered in the case, or any part thereof. When only a part of the decree is appealed from the notice of the appeal should so state, and shall also in that case specify the portion or part of the decree appealed from. Upon filing of such notice of appeal the cause shall be deemed to be appealed to the supreme court of the Territory: *Provided, however*, That the party or parties appealing as aforesaid, shall, within sixty days aforesaid, enter into an undertaking, to be approved by the district court, or judge thereof, and to be given to all parties in said suit or proceeding, other than the parties appealing, and to be in such an amount as the court or said judge shall fix, conditioned that the parties giving their said undertaking shall prosecute their appeal to effect, and without unnecessary delay, and will pay all costs and damages which the parties to whom the undertaking is given, or either or any of them may sustain in consequence of such appeal. [S. L. 1886, ch. 61, § 18.]

SEC. 1349. The order last aforesaid shall be entered of record, and the appellant or appellants shall cause a certified copy thereof to be served on each of the appellees, by delivering the same to him or her, if he or she may be found, or otherwise serving the same, in manner the same, as may be provided for serving summons from the district court by the laws then in force. [S. L. 1886, ch. 61, § 19.]

SEC. 1350. The appellant or appellants shall, within six months after the appeal be allowed as aforesaid, file in the office of the clerk of the supreme court of this Territory a certified transcript of the proceedings had in the case in the district court containing the pleadings and the statements of the parties filed herein and all evidence of record offered on the hearing of the cause, or so much thereof as shall effect the appropriation of water claimed by the means of construction, enlargement, or reenlargement of the several ditches, canals, and reservoirs mentioned in the order allowing the appeal. When the evidence has been taken in the open court, or before the judge, in vacation, such evidence, or the substance thereof, reduced to writing and signed by the judge, or in case notes of said testimony have been taken by the official stenographer, a transcription of the same, signed by the stenographer and attested by his official seal, filed with the clerk of the court, shall be deemed a record of the evidence taken in said court. [S. L. 1886, ch. 61, § 20.]

Sec. 1351. The supreme court, in all cases heard before it under this chapter, shall, where it can properly be done, render such decree as the court, or the judge below, should have rendered. It may either reverse or modify the decree of the court or judge below, and in cases where the decree of the court below is reversed, in whole or in part, it may direct the court below as to its further proceedings therein. [S. L. 1886, ch. 61, § 21.]

Sec. 1352. No claim of priority of any person, association, or corporation on account of any ditch, canal, or reservoir, as to which he, she, it, or they have failed or refuse to offer evidence, under any adjudication herein provided for, shall be regarded by any water commissioner in distributing water in times of scarcity thereof, until such time as such party shall have by application to the court having jurisdiction obtained leave and made proof of the priority of right to which such ditch, canal, or reservoir shall be justly entitled, which leave shall be granted in all cases upon terms as to notice to other parties interested, and upon payment of all costs, and upon affidavit or petition sworn to, showing the rights claimed, and the ditches, canals, and reservoirs, with the names of the owners thereof, against which such priority is claimed, nor until a decree adjudging such priority to such ditch, canal, or reservoir has been entered, and certificate such as mentioned in section thirteen hundred and forty-six shall have been issued to claimant and presented to the water commissioner. [S. L. 1886, ch. 61, § 22.]

Sec. 1353. No person, association, or corporation representing any ditch, canal, or reservoir shall be permitted to give or offer any evidence before said court until he, she, it, or they shall have filed a statement of claim in substance the same in all respects as is required to be filed under the provisions hereof. [S. L. 1886, ch. 61, § 23.]

Sec. 1354. The district court, or judge thereof, in vacation, shall have power to order for good cause shown, upon terms just to all parties, and in such manner as may seem meet, a re-argument or review, with or without additional evidence, of any decree made under the provisions of this chapter, whenever said court or judge shall find from the cause shown for that purpose by any party or parties feeling aggrieved, that the ends of justice will be thereby promoted, but no such review or reargument shall be ordered unless applied for by petition or otherwise within two years of the time of entering the decree complained of. [S. L. 1886, ch. 61, § 24.]

Sec. 1355. Persons desiring to construct and maintain reservoirs for the purpose of storing water shall have the right to take from any of the natural streams of the Territory and store away any unappropriated water not needed for immediate use, for domestic or irrigation or other beneficial purposes, to construct and maintain ditches, canals, flumes, or tunnels, for carrying such water to and from such reservoirs, ditches, canals, tunnels, and flumes, in the same manner provided by law for the condemnation of lands for right of way for ditches: *Provided*, No reservoir with embankments or a dam exceeding ten feet in height shall be made without first submitting the plans thereof to the county commissioners of the county in which it is situated, and obtaining their approval of said plans: *And provided, further*, That no such reservoir shall be constructed or made in or across the channel of any natural and running stream. [S. L. 1886, ch. 61, § 25.]

Sec. 1356. The owners of reservoirs shall be liable for all damage arising from leakage or overflow of the waters therefrom, or by floods caused by breaking of the embankments of such reservoir. [S. L. 1886, ch. 61, § 26.]

Sec. 1357. Every witness who shall attend before the court, or the judge thereof in vacation, or before the person appointed to take testimony, in the causes provided for in this chapter, under subpœna, by request of any party, shall be entitled to the same fees and mileage as witnesses in civil cases in the district court, and shall be paid by the party requiring his testimony. [S. L. 1886, ch. 61, § 27.]

Sec. 1358. It shall not be necessary for any corporation heretofore organized and now existing, or for any corporation hereafter organized, under the laws of this Territory, which has heretofore, or shall have hereafter constructed, operated, or maintained any ditches, canals, flumes, tunnels, or reservoirs, or other appropriations of water, for the purpose of irrigation, mining, manufacturing, domestic uses, or for any beneficial purpose whatever, to incorporate as a ditch company, or companies, if the objects or purposes for which such corporation shall have been formed or incorporated, imply, permit, or make necessary, or advantageous, such use or uses of water; and such corporation for all the purposes of this chapter shall have all the rights of a natural person as defined herein, and shall have its rights determined in the same manner: *Provided*, No priority of water right shall take from any city or town the water required for the use of the the residents thereof. [S. L. 1886, ch. 61, § 28.]

SEC. 1359. Said water commissioners shall so divide, regulate, and control the use of the water of all streams within their respective districts in such manner, as near as may be, as will prevent unnecessary waste of water, and to that end such commissioners shall so shut and fasten the head-gate or gates of all ditches so that no more water will flow into said ditch than is actually required and will be used for the uses or purposes for which such water was appropriated, and any person who may be injured by the action of any water commissioner or by his failure to act pursuant to this chapter, may resort to any court of competent jurisdiction for such relief as he may be entitled to. [S. L. 1886, ch. 61, § 29.]

SEC. 1360. It shall be the duty of every person, corporation, or company, who shall construct, maintain, or operate any ditch or canal under the provisions of this chapter to construct and maintain, at the point and place where the water is diverted from its natural channel, some fit and proper obstruction whereby all fish will be prevented from entering said ditch or canal. Any person, company, or corporation violating the provisionsof this section shall be adjudged guilty of a misdemeanor, and on conviction thereof shall be punished by a fine of not more than one hundred dollars or by imprisonment in the county jail not less than ten nor more than sixty days, or by both such fine and imprisonment. [S. L. 1886, ch. 61, § 30.]

SEC. 1361. This chapter shall in no wise be construed as impairing or abridging any rights already vested in any person or persons, company or corporation, by virtue of the law heretofore in force. [S. L. 1886, ch. 61, § 31.]

CHAPTER 55.

IRRIGATION—APPROPRIATION OF WATER—TERRITORIAL ENGINEER.

AN ACT creating the office of Territorial engineer and concerning appropriation of water.

Be it enacted by the Council and House of Representatives of the Territory of Wyoming:

SECTION 1. There shall be a Territorial engineer, who shall be appointed by the governor, by and with the consent of the legislative council; he shall hold his office for the term of two years, commencing on the first day of April, A. D. eighteen hundred and eighty-eight, and until his successor shall be appointed and shall have qualified.

The governor may at any time, upon good cause being shown, remove the Territorial engineer, and fill the vacancy occasioned by such removal from office.

The Territorial engineer shall receive a salary of two thousand and five hundred dollars per annum, payable in monthly installments by the Territorial treasurer, upon warrants drawn by the Territorial auditor.

The Territorial engineer shall keep his office at the Territorial capitol, in a room in the capitol building, to be set aside for his use by the governor.

Before entering upon the duties of his office he shall take and subscribe an oath before some officer authorized by the laws of this Territory to administer oaths, to faithfully perform the duties of his office, and file with the secretary of the Territory said oath and his official bond, in the penal sum of five thousand dollars, with not less than two sureties to be approved by the governor of the Territory, and conditioned for the faithful discharge of the duties of his office, and for delivering to his successor, or other officer appointed by the governor to receive the same, all moneys, books, and other property belonging to the Territory then in his hands, or under his control, or with which he may be legally chargeable, as such officer. No person shall be appointed as such Territorial engineer who is not known to have such theoretical knowledge and practical skill and experience as shall fit him for the position.

SEC. 2. The Territorial engineer shall have general supervision of the diversion and division of the water of the various natural streams in the Territory, and shall have supervision of the work of the water commissioners of the different water districts of the Territory, and shall do and perform any and all work for the Territory which comes within the nature of his profession as an engineer, when called upon by the governor to do so.

SEC. 3. The Territorial engineer shall make, or cause to be made, careful measurements and calculations of the maximum, minimum, and ordinary flow, in cubic feet per second of time, of the waters flowing in each stream from which water shall be drawn for irrigation purposes, commencing such work upon those streams most used for irrigation; he shall collect facts and make a report as to a system of reservoirs for the storage of waters in those portions of the Territory where such a system is practicable, stating in such report the location, capacity, and cost of such reservoirs: he shall become conversant with the water-ways of the Territory, and needs of the Territory as to irrigation matters, and in his report to the governor he shall make such suggestions as to the amendment of existing laws, or the enactment of new laws, as his information and experience may suggest; and he shall keep full and proper records of his works, observations, and calculations, all of which shall be the property of the Territory.

Sec. 4. The Territorial engineer shall, onrequest of any party interested, measure and ascertain the carrying capacity of any ditch used for irrigation or other beneficial purposes, which may be now, or which may hereafter be constructed or enlarged, and give to the party or parties requiring such services an official certificate of the size and carrying capacity of such ditch, expressed in cubic feet per second of time, as he shall find it at the time of measuring the same. For such services he shall be entitled to receive from the party or parties requiring the same his per diem charges, not exceeding ten dollars per day, and his reasonable traveling expenses: *Provided*, That all per diem charges for such services received by the Territorial engineer shall be delivered by him to the Territorial treasurer, who shall credit the same to the general fund. If the applicant or applicants for such engineer's certificate shall state in writing to the engineer that the ditch to be measured is so remote from the office of the engineer as to render the expense of the engineer's personal examination too great, or if in the engineer's judgment such ditch is too far distant to prevent him, consistently with his public duties, to make such personal examination, it shall in such cases be his duty to appoint some competent civil engineer, residing in the vicinity of such ditch, to make a sworn statement setting forth the width on top and bottom, depth, grade, and slope of the bank of such ditch or its enlargement, and all such other data concerning such ditch so to be measured as the Territorial engineer shall direct. Such civil engineer shall receive for his services such sum as may be agreed upon between himself and the party requiring his services, but in the absence of any agreement in writing such compensation shall not exceed ten dollars per day and his reasonable traveling expenses. The Territorial engineer shall furnish the person so appointed with blank certificates upon which to enter the necessary data concerning the ditch or its enlargement, so to be measured, which blank shall be properly filled out and verified by the oath of the party making such measurements and returned to the Territorial engineer, who shall make his own calculations of the carrying capacity of such ditch or enlargement, expressed in cubic feet per second of time, and certify to the same. The certificates provided for in this section shall set forth the time of making the measurement, the location of the headgate of the ditch measured, the name of the natural stream of water from which such ditch draws its supply of water, the width of such ditch both on top and on bottom, its depth and grade, and its carrying capacity expressed in cubic feet per second of time, and also the name of the ditch and of the owner or owners thereof, if known. All such certificates shall be recorded at length in the office of the said Territorial engineer, and copies of such record duly certified to by the said engineer, shall be received in all the courts of this Territory, as prima facie evidence of the fact therin set forth, as hereby required.

Sec. 5. The Territorial engineer, with the consent of the governor, shall have power to employ assistants at an expense not to exceed one thousand dollars in any one year, who shall be paid out of any moneys appropriated for that purpose, on the certificate of said Territorial engineer, approved by the governor, showing the reason for such employment, the services rendered, and the amount thereof, and on presentation of such certificate to the Territorial auditor, by the person entitled thereto, he shall issue his warrant on the territorial treasurer for the amount thereof to be paid out of any appropriation, as aforesaid, and not otherwise.

Sec. 6. When the Territorial engineer is called away from his office in the discharge of his public duties, he shall be entitled to his actual traveling expenses, which shall be paid out of any money appropriated for that purpose, on the certificate of the said engineer; such certificate shall be presented by the said engineer to the Territorial auditor, who shall thereupon draw his warrant upon the Territorial treasurer for the amount thereof, to be paid out of such appropriation: *Provided*, That this section shall not be so construed as to authorize the payment of traveling expenses to said engineer when called away from his office to perform any of the work mentioned in section four of this act.

Sec. 7. The appropriator of any of the public waters in this Territory shall construct and maintain, under the direction of the Territorial engineer, a flume or other measuring device, at or as near the head of his ditch as is practicable, for the purpose of assisting the water commissioners in determining the amount of water that may be turned into the ditch or the amount that may be by his ditch diverted from the stream. In case any owner or appropriator of public waters that have been adjudicated upon neglect or refuse to put in such measuring device, after thirty days' notice to do so by the Territorial engineer, the said engineer may direct the water commissioner, of the district in which the ditch may be situate to put in such flume or measuring device, which being done by the water commissioner, he, the said commissioner, shall present the bill of the cost of such flume or measuring device to the owner or owners of the ditch, and if such owner or owners shall refuse or neglect, for three days after presentation of such bill, to pay the same, the said water commissioner may maintain a civil action in his own name, in any court of the Territory, for the recovery of the same, with all accruing costs. Said suit shall be prosecuted by the county and prosecuting attorney for the county wherein such suit may be brought, free of any charge against said commissioner.

SEC. 8. The Territorial engineer shall prepare and render to the governor yearly, and oftener if required, full and true reports of his work, touching all the matters and duties devolving upon him by virtue of his office, which report shall be delivered to the governor on or before the thirtieth day of November in each year, in order that the same may be laid before the legislative assembly at its regular sessions.

SEC. 9. In all cases in which the priorities to the right to the use of the waters of any of the streams of this Territory have have been adjudicated by any of the district courts of this Territory under the provisions of chapter two of title nineteen of the Revised Statutes of Wyoming, it shall be the duty of the clerk of the district court wherein such adjudication may have been made to forward a certified copy of such decree to the Territorial engineer immediately after the rendering of a decree in the matter of such adjudication, and for such copy there shall be paid to the said clerk, out of the treasury of the county wherein such decree was rendered, compensation at the rate of ten cents for each one hundred words contained in such decree. On receipt of such copy of such decree it shall be the duty of the Territorial engineer to cause the same to be recorded at length in a suitable book, to be provided for that purpose, and as soon thereafter as practicable to forward to the water commissioner of the water district wherein the stream adjudicated upon is situated a statement showing the title of the court in which such decree was rendered, the date of the decree, the name of each ditch the priority of which has been by such decree determined, its capacity, showing the width, depth, and grade of the said ditch and the quantity of water per second of time to which said ditch is declared by such decree to be entitled, to be expressed in cubic feet per second of time, and thereafter, in the supervision of the distribution of the waters of such streams by said ditches so adjudicated upon it shall be the duty of the said water commissioner to be guided by such statement. It shall be the duty of the Territorial engineer to procure and cause to be recorded in his office a description of the flume or other measuring device at the head of each ditch so adjudicated upon, showing the width, depth, and grade of each flume or other measuring device, and to calculate and determine the quantity of water, expressed in cubic feet per second of time, which will flow through such flume or other measuring devide at various depths, and furnish the proper water commissioner with a statement of the same.

SEC. 10. The water of every natural stream not heretofore appropriated, within the Territory of Wyoming, is hereby declared to be the property of the public, and the same is hereby dedicated to the use of the people of said Territory, subject to appropriation as hereinafter provided.

SEC. 11. Every person, company, or corporation hereafter constructing, enlarging, or extending any ditch, canal, or reservoir for irrigation or other beneficial purposes, and intending to use or appropriate any water from any natural stream within a water district for such purposes, shall, within ninety days after the commencement of the construction, enlargement, or extension of such ditch, canal, or reservoir, file and cause to be recorded in the office of the county clerk and ex-officio register of deeds of the county in which is situated the district court having jurisdiction of all questions concerning the priority of rights to the use of water in such water district, a statement of claim under oath, setting forth the name or names, together with the post-office address of the owner or owners of any such ditch, canal, or reservoir; the name thereof, if any, and if without a name, the owner or owners shall adopt a name to be therein stated, by which such ditch, canal, or reservoir shall thereafter be known; the number of the water district in which the same is situated; a description of such ditch, canal, or reservoir, as to location of head-gate and the general course of such ditch; the name of the natural stream from which such ditch, canal, or reservoir draws its supply of water; the length, width at top and bottom, depth, grade, and carrying capacity thereof, expressed in cubic feet per second of time, as near as may be; the time, giving the day, month, and year when work was commenced thereon by original construction, enlargement, or extension, as the case may be, and likewise the date when water was actualy appropriated therefrom for irrigation and other beneficial purposes; the number of acres lying under and being, or proposed to be, irrigated by water therefrom, and a map or plat on a scale of not less than one inch to the mile, showing the location or route of such ditch, canal, or reservoir, and the natural stream from which it draws its supply of water, and also the legal subdivisions of land through which they flow: *Provided,* That in case the said statement gives the direction or route of such ditch by courses and distances, according to the field-notes of the survey thereof, it shall not be necessary to include in any such statement the map or plat above referred to. Such statement shall be signed by the person owning such ditch, canal, or reservoir, or, in case of a copartnership, by any member thereof, for and in behalf of such copartnership, or in case of a corporation, by the president or secretary thereof, and such statement shall be recorded as aforesaid in a book to be kept for that purpose.

SEC. 12 If the owner or owners of any such ditch, canal, or reservoir shall prosecute the work of construction thereon diligently and continuously until completed, and shall otherwise comply with the provisions of law, such owner or owners shall, as regards the owner or owners of all other ditches subsequently constructed and drawing their supply of water from the same stream, have a priority of right to the use of such water from and after the date of the commencement of the construction thereof, but not otherwise. The beginning of all necessary surveys of such ditch shall be considered as the commencement of such work of construction.

SEC. 13. When the waters of any natural stream are not sufficient for the service of all those desiring the use of the same, those using the water for domestic purpose shall have preference over those claiming water for any other purpose, and those using the water for agricultural purposes shall have the preference over those using the same for manufacturing purposes.

SEC. 14. The priority of right to the use of such water shall be limited and restricted to so much thereof as may be necessarily used and appropriated for irrigation or other beneficial purposes as aforesaid, irrespective of the carrying capacity of the ditch, and all the balance of the water not so appropriated shall be allowed to run in the natural stream from which such ditch draws its supply of water, and shall not be considered as having been appropriated thereby; and in case the owner or owners of any such ditch, canal, or reservoir shall fail to use the water therefrom for irrigation or other beneficial purposes, or shall refuse to furnish any surplus water to the owner or owners of lands lying under such ditch as hereinafter provided, during any two successive years, they shall be considered as having abandoned the same, and shall forfeit all water rights, easements, and privileges appurtenant thereto, and the waters formerly appropriated by them may be again appropriated for irrigation and other beneficial purposes the same as if such ditch, canal, or reservoir had never been constructed; neither shall the owner or owners of any such ditch, canal, or reservoir have any right to receive from others any royalty for the use of the water carried thereby, but every such owner or owners having a surplus supply of water and furnishing the same to others from any ditch, canal, or reservoir as hereinafter provided, shall be considered common carriers and shall be subject to the same laws that govern common carriers.

SEC. 15. The owner or owners of any such ditch which carries a greater quantity of water than the owner or owners thereof necessarily use for irrigation and other beneficial purposes in connection with their own lands shall, when application is made to them for that purpose, furnish such surplus water at reasonable rates to the owners of lands lying under any such ditch for the purpose of reclaiming such lands and rendering the same productive, and in case of refusal so to do the owner or owners of any such ditch may be compelled by injunction suit to furnish such water on such terms as to the court may seem meet and proper: *Provided,* That the board of county commissioners in their respective counties shall have power, when application is made to them by either party interested, to establish reasonable maximum rates to be charged for the use of water, whether furnished by individuals or corporations.

SEC. 16. The cubic foot of water per second of time shall be the legal standard for the measurement of water in this Territory, both for determining the flow of water in natural streams and ditches and also for the purpose of distributing water therefrom.

SEC. 17. Nothing in this act contained shall in any wise interfere with any prior right to the use of said water; neither shall the owner or owners of any such ditch, canal, or reservoir who have heretofore complied with the laws relating thereto enacted by the ninth legislative assembly of Wyoming be required to file any additional statement of claim under the provisions of this act.

SEC. 18. Section thirteen hundred and forty-three of the Revised Statutes of Wyoming and all laws and parts of laws inconsistent herewith are hereby repealed.

SEC. 19. This act shall take effect and be in force from and after its passage.

Approved March 8, 1888.

CONSTITUTIONAL PROVISIONS.

[FILED WITH THE COMMITTEE BY JOHN K. JEFFREY, SECRETARY OF STATE CONSTITUTIONAL CONVENTION.]

ARTICLE I.—*Declaration of rights.*

SEC. 31. Water being essential to industrial prosperity, of limited amount, and easy of diversion from its natural channels, its control must be in the State, which in providing for its use shall equally guard all the various interests involved.

SEC. 32. Private property shall not be taken for private use unless by consent of the owner, except for private ways of necessity, and for reservoirs, drains, flumes, or ditches on or across the lands of others for agricultural, mining, milling, domestic, or sanitary purposes, nor in any case without due compensation.

ARTICLE VIII.—*Irrigation and water rights.*

SECTION 1. The water of all natural streams, springs, lakes, or other collection of still water, within the boundaries of the State, are hereby declared to be the property of the State.

SEC. 2. There shall be constituted a board of control, to be composed of the State engineer and superintendents of the water divisions, which shall, under such regulations as may be prescribed by law, have the supervision of the waters of the State and of their appropriation, distribution, and diversion, and of the various officers connected therewith. Its decisions to be subject to review by the courts of the State.

SEC. 3. Priority of application for beneficial uses shall give the better right. No appropriation shall be denied except when such denial is demanded by the public interests.

SEC. 4. The legislature shall by law divide the State into four water divisions, and provide for the appointment of superintendents thereof.

SEC. 5. There shall be a State engineer, who shall be appointed by the governor of the State and confirmed by the senate; he shall hold his office for the term of six years, or until his successor shall have been appointed and shall have qualified. He shall be president of the board of control, and shall have general supervision of the waters of the State and of the officers connected with its distribution. No person shall be appointed to this position who has not such theoretical knowledge and such practical experience and skill as shall fit him for the position.

ARTICLE X.—*Corporations.*

SECTION 1. The legislature shall provide for the organization of corporations by general law. All laws relating to corporations may be altered, amended, or repealed by the legislature at any time when necessary for the public good and general welfare, and all corporations doing business in this State may as to such business be regulated, limited, or restrained by law not in conflict with the Constitution of the United States.

SEC. 2. All powers and franchises of corporations are derived from the people, and are granted by their agent, the government, for the public good and general welfare, and the right and duty of the State to control and regulate them for these purposes is hereby declared. The power, rights and privileges of any and all corporations may be forfeited by willful neglect or abuse thereof. The police power of the State is supreme over all corporations as well as individuals.

SEC. 3. All existing charters, franchises, special or exclusive privileges, under which an actual and bona fide organization shall not have taken place for the purpose for which formed and which shall not have been maintained in good faith to the time of the adoption of this constitution, shall thereafter have no validity.

FURTHER STATEMENT OF ENGINEER ELWOOD MEAD.

The CHAIRMAN. Do you wish to add anything to what you have already said?

Mr. MEAD. I wish to say that there is a condition of affairs that prevails here that your questions do not touch directly. I do not know whether it is peculiar to this territory or not, but I think it is important that it should be understood. The land laws at the present time make it difficult for the individuals who take the land to combine to make a ditch. A large expensive ditch takes a large amount of capital to build it, and a considerable length of time to complete its construction so that the people can get water from it. The settlers will starve to death before the ditch can be completed because they can not raise anything on the land while they are doing it.

The CHAIRMAN. That is not always the case. I have known instances where individuals, by combining together, have gone into gigantic enterprises.

Mr. MEAD. They can not do it here. I believe it is best for the settler and best for every one that these ditches should be built in advance of settlement. If we could by some mean secure the proper location for large canals, so that a few canals would distribute the water, we would get the water on better land, there would be a great saving in the water supply and it would be a manifest advantage to the people who came here to settle. I have seen many attempts by actual settlers to settle on these arid lands. They had to wait until the ditch was built. I have seen too much of the privation of their families to believe that that is a satisfactory method. If the ditch were built, so that a man could at once begin farming, there would be no suffering.

Senator JONES. What is your plan?

Mr. MEAD. I want to say first, what has been the development of this Territory, before I give the plan. We have found it impossible and unsatisfactory to combine under the present system of land owning. The result has been that people have combined and built a ditch to water merely their own claims. We have in this Territory to-day probably three thousand ditches built, though there are on record only two thousand five hundred and fifty. The great majority of those are individual ditches. Each settler who went on a stream built an individual ditch to water his own claim. Another settler came and did likewise. I can show you on the office maps twenty-six ditches on one stream in one township. The Territory is charged with a division of water between those several claimants. Take a stream 80 miles long and undertake to divide the water between eighty claimants, and you will understand the difficulty. That plan is immensely wasteful of water and of everything. It is very difficult to maintain those ditches. The average expense of watering land by that system is over $10 an acre. If we could have highland channels that would water those areas, it should not cost half that much to get the water on the land, and more water would get on it. My idea is to turn this land over to the Territory or to the local government, under such regulations as will secure its final disposal to actual settlers, and the Territory could put the companies under such restrictions as would secure ditches, and could also manage the work of their being settled by actual settlers. We would then have a system that could be intelligently planned.

The **CHAIRMAN.** Do you know of any State or Territory that has managed its lands well that has adopted that plan?

Mr. **MEAD.** Yes, I think that on the whole the management of the land by Colorado has been fully as wise as the management of the land by the Government.

Senator **JONES.** Would you advise the Government to authorize the States to make any other disposition of those lands except by homestead settlements?

Mr. **MEAD.** This would be my plan: To turn these lands over to the States. The proper procedure would then be, either for the State or the National Government to locate these canals on the streams, say where they ought to be. Then it can make a close estimate as to the cost of construction and what it would cost to operate the same. I would then allow private capital to build that ditch, and would permit the companies to charge (to have an agreement in the first place that they might charge) a fair rental for the water, and I would provide for that to be continued subsequently, if necessary. Then in regard to the land, I would do this: I would permit the ditch companies, perhaps, to have the management of the settlement. I would make them colonization agents, but I would have the State itself pass the title to the settler. I would not make any title absolute until I knew that it was a bona fide settlement; but I would put the settlement of it in the hands of the ditch companies. They will have the greatest interest in securing settlement. What the ditch company needs is an assurance that the land will be settled when the water is there. They want to be in a position so as soon as the ditch is built, to run it the next year to its full capacity. If they can do that they can furnish water at a much less rental.

Senator **JONES.** That is true; but get back to the main question. Would you authorize or advise the National Government to convey this land to the State for any purpose except to be used for homesteads?

Mr. **MEAD.** No; nothing else.

The **CHAIRMAN.** Then the State would get nothing on earth by the conveyance from the Government to the State, because the land is now within the State, and it is already subject to homestead settlement.

Mr. **MEAD.** I do not understand your question. Do you mean that you would not permit the State to derive any revenue whatever from this land?

Senator **JONES.** I want to know whether you would allow the State to mortgage the land to the ditch companies, for instance?

Mr. **MEAD.** I would not allow the Government to transfer to the State only under the condition that it was to be disposed of to an actual settler and cultivator; but I would permit the State to charge for it and sell it.

Senator **JONES.** Then your idea is to turn the land over to the States to enable them to create a fund to build the ditches?

Mr. **MEAD.** To create a fund to manage and, if necessary, to create a fund to build the ditches. I state in my report that I do not think reservoirs can be built unless conditions change. If they are built they must be subsidized.

The **CHAIRMAN.** They are building them in some places.

Mr. **MEAD.** That is my judgment in regard to this Territory. There are but few favored places where they will be built, but I have in view a comprehensive system. The places where reservoirs can be built as a business proposition are restricted.

The **CHAIRMAN.** You speak of selling the water. Do you think it will be advantageous to have the water owned and controlled by corporations?

Mr. MEAD. No; the water would not be owned at all. It would be a common carrier that had built the ditch and that carrier could only make a charge for transportation.

Senator JONES. Suppose it did not result as you anticipate it would, what would happen?

Mr. MEAD. In what way do you mean?

Senator JONES. How is the ditch company to get its money? Suppose this State makes a contract for a company to go out into one of the valleys and expend a million dollars to bring water on the land; that money is expended, and suppose the place did not settle up, then what?

Mr. MEAD. The company would lose. But the difficulty at the present time is that the ditch companies have no control over settlement.

Senator JONES. And they ought not to have.

Mr. MEAD. I should not want the ditch companies to have it in their power to prevent settlement, but I would wish them to assist settlement.

Senator JONES. I am something of a crank on the idea that the remaining lands of the United States should be made into homes.

Mr. MEAD. That is right.

The CHAIRMAN. How would you regulate the price of water?

Mr. MEAD. Land upon which there is no ditch in this Territory will have a price varying from 15 cents to $1.50 per acre—I mean grazing lands. If you construct a ditch over such land, say a large ditch, so as to make it certain that there will be a considerable settlement there, that land is ultimately reclaimed, and the result will be that the land will enhance in value from the construction of that ditch from $5 to $15 per acre. Suppose a ditch company goes in at the present time to build that ditch and make it possible for the pre-emptor or homesteader or any one with a timber claim to go and file on the land, settle down, and get a title to the land, without in any way contributing to that enterprise of the ditch company, it makes it possible for him to reap that unearned increment.

Senator JONES. But he does not get any value from the ditch.

Mr. MEAD. Suppose a man files on the pre-emption claim and lives on it six months; if that land enhances in value he can sell it. Now, does he not reap the benefit?

Senator JONES. Not a bit. He has to get the water. The possibility of getting the water is one thing, but when he gets the water he has to pay for it. The water may be there and, when he buys the ditch, he figures that up in connection with the possibility of getting the water. But the truth is there is not any value in any of this land. The value is in the water.

Mr. MEAD. Exactly; and we want a system that will distribute that water to the best advantage and save it.

Senator JONES. There is no doubt that there ought to be some changes made.

REPORT SUBMITTED BY ELWOOD MEAD, TERRITORIAL ENGINEER.

IRRIGATION IN WYOMING.

No. I.

1.—Water Supply.

The mountains are the great condensers of moisture and the conservators of our summer water supply. The more extensive and elevated these are the more abundant and long-continued the summer discharge. The extent of the mountain area is therefore as important as that of the plain in estimating the ultimate extension of our irrigated area.

The mountains contributing to the water supply of this Territory are the main range of the Rockies in Colorado and southern Wyoming, the Big Horn and Wind River Mountains in the north, and the mountains of Uinta County in the west. In addition there are the minor ranges, including the Sweetwater and Rattlesnake Mountains in the central portion, the Laramie Range in the east, and the Black Hills Range in the northeast. Taken as a whole, the mountains which form the culmination of the water-sheds of our streams are equal in area to fully one-third of the Territory, or about 35,000 square miles, or 22,400,000 acres.

It is difficult to arrive at a satisfactory conclusion as to the amount of precipitation which falls on these mountains owing to no regular observations having been kept. That it is unusually heavy is known. The reports of the explorations of the Yellowstone Park region state that the snow-fall of that section is above the average for the Rocky Mountains. From this and other data I am led to believe that the rain and melted snow must cover these mountain summits to an average depth of between 2 and 3 feet, giving approximately 60,000,000 acre-feet of water deposited each year. If we suppose that two-thirds of this disappears by evaporation and in other ways there still remains 20,000,000 acre-feet passing down the streams and available for irrigation. Taking the average duty of water at 1 cubic foot per second for 80 acres, this is sufficient water to serve 10,000,000 acres, and it only requires the utilization of the resources here to see our agricultural area extended to this limit.

2.—Location and Distribution.

The location of these mountain areas is such as to cause the Territory to be exceptionally well watered. The streams flow down from their slopes in every direction and penetrate all portions. Although there are over four hundred streams from which water is diverted for irrigation, they form themselves into four natural divisions or drainage systems. These divisions, although differing from the water districts defined by law, will, for convenience, be used in this statement, being designated as 1, 2, 3, and 4.

Of these, the Platte River and its tributaries form the first, the North Platte being the principal stream, and is one of the most important leaving the eastern slope of the Rockies. Having its source on the western slope of Long's Peak, in Colorado, it drains an extensive mountain area before entering this Territory. Owing to its detour to the north it waters a large district within our borders; its length from the Colorado to the Nebraska border being about 350 miles. Of this distance there is probably no section 50 miles in length where its waters can not be diverted, but owing to the expense involved in constructing the necessary head works to withstand the floods of a stream of such volume the principal development has occurred on its tributaries. Maps showing the ditches on three of these streams, the Laramie River, Horse and Crow Creeks, accompany this statement.

Division No. 2 comprises all the streams east of the Big Horn Mountains. In this division irrigation has attained its greatest success and importance, the counties of Johnson and Sheridan having a fine water supply from the streams flowing from the Big Horn Mountains. The rapid fall of this region to the east and north offers unusual facilities for diverting water; a peculiar feature in this section being the large number of canals carrying water across the divides from the stream into the valley of another. The stability of the water supply and the enormous fall which can be readily obtained marks this as a suitable location for the development of extensive water-powers when the country is made accessible by railroads. As yet the development has been restricted by the lack of capital to undertake the construction of large canals to rent water, but there are fine opportunities throughout this region for such enterprises. The main reason for the delay in their inauguration being stated in my main report.

The third division includes the Big Horn River and its tributaries. It is one of the best watered portions of the arid region, as it drains both the Wind River and Big Horn Mountains. Owing to the enormous discharge of these streams, and the fact that the uplands can only be watered by costly works, the settlers have had thus far but little apprehension of any scarcity in the supply, and have consequently been negligent in recording their ditches. Hence the statement of the ditches diverting water from the streams of this division, given further on, is much below the truth.

The Green, Bear, and Snake Rivers are the tributaries from the fourth division. Considerable work has been done on Bear River and a few of the tributaries of Green and Snake Rivers, but this division as a whole, like number 3, is practically untouched as compared to the possibilities here presented. The large surplus of water here has operated, as in division 3, to make ditch owners neglect to record their claims. The records of Sweetwater County being so manifestly below the truth, I have omitted all statistics from that county.

The valleys of the Green and Big Horn offer to-day the best opportunities for the construction of a system of irrigation works, according to a pre-arranged plan, of any section with which I am familiar. To a large water supply and immense tracts of valuable public land there is added the total absence of vested rights to interfere with the construction of the necessary works. It is to be hoped that suitable measures may be taken for the designing and construction of such system of works. It would prove a valuable object-lesson when placed in contrast with some of our former efforts.

No attempt has been made to estimate the extent of irrigation possible in each section, since the absence of stream gaugings gives no data on which to base one.

3.—IRRIGATION WORKS.

Under the Territorial laws the owners of the ditches are required to file, in the offices of the county clerks of the various counties, a statement showing their capacity, location, acreage watered, and such additional facts as are required to make a complete record. As there is no penalty attached to a failure to comply with this requirement many ditches are not recorded, probably five hundred in the whole Territory, and, owing to defective blanks used at first, many that are recorded have made incomplete statements, so that it is impossible to state accurately the area reclaimed. Below is given a table giving the present extent of our irrigation development as shown by the recorded statements, the majority of which have been verified by engineer's certificate as to the dimensions and capacity. It is an extraordinary record when it is remembered that it is principally the work of the past ten years. In extent the irrigated area exceeds the average of the land farmed in each of the New England States, and should forever put at rest the cavil or question as to the ultimate wealth and greatness of this commonwealth. If the pioneers in this work can, unaided and under great disadvantages, produce such results, what may not be accomplished through the intervention of ample capital or of State or national aid?

4.—EXPENSES OF RECLAIMING LAND.

Some time since there was issued from this office a letter of inquiry to ascertain the cost of reclaiming the arid lands. These inquiries were addressed to farmers of known intelligence and of considerable practical experience. The replies are of great value in throwing light on this subject, and I have had them arranged and copied, and they are herewith submitted as Appendix B.

Representing the views of all sections of the Territory, and based on actual experience their statements are entitled to a careful consideration, especially as to some of the perplexing questions which now confront us. While the views as to the proper course to be adopted are somewhat at variance there is a unanimity of sentiment as to the desirability of a more liberal policy in respect to the disposal of the public land. Their statements are also valuable in indicating the amount of money which has been expended in reclaiming the land already under ditches. The amount varies in the different statements from $5 to $25 per acre, so that $10 would be a low average, making the total expenditure for this work over $15,000,000.

5.—TERRITORIAL SUPERVISION.

The irrigation laws of this Territory are very largely copied from those of Colorado, but are in some respect in advance of the parent legislation.

The control of the water by the State is affirmed, and ditches are by law made common carriers. Priority of use gives the better right, and provision is made for settling disputed cases in the courts.

The engineer is the chief executive officer of the system and is charged with the "supervision of the diversion and distribution of the public waters, and of the officials connected therewith." The Territory is divided into nine water districts, in each of which a water commissioner controls the diversion of the water. The important defect of the system is the failure to exercise any control over the streams prior to construction of ditches, and to take steps to secure the proper location and construction of distributing works. The constitutional convention now in session has, however, provided a remedy for this when we become a State.

6.—Future Development.

The problems to be solved in connection with this subject are the obtaining of means for the construction of canals of too great magnitude and expense for combinations of farmers to attempt, and the improvement and utilization of storage reservoirs to hold the waste water of winter and the surplus from the summer floods. There are great possibilities in either direction. On all the important streams there are splendid opportunities for the construction of extensive works to water the uplands, and an abundance of water to supply them when built. With the building of these will come an era of growth and prosperity to our agriculture of which we can scarcely form a conception at the present time. These canals can and will under proper conditions be built by individual or co-operative enterprise, but I am persuaded that if any extensive system of reservoirs is to be brought into use it must be under different auspices.

On many of our streams is already felt the pressing need of an auxiliary summer's supply which the reservoir would furnish, but the expense of improving and making available these storage basins prevents the work being undertaken as a business enterprise. The value of the land and of the products grown thereon will only justify a certain outlay for water, and this, with us, must always be less than in the semitropical portions of the country where the higher-priced products will warrant a far greater outlay.

There are sites for such storage basins on nearly every stream and there would come an immense extension of cultivated area from their improvement. The chief beneficiary of such extension is the State and nation, since it results in an increase of the productive capacity of the country and makes a perpetual addition to the public revenue. I believe that the benefits to be derived therefrom will amply warrant and justify the giving of aid in this work by the National Government, and in fact renders this course the only sound public policy.

Should such aid be extended, it will result in such an irrigation development here as will, with the exception of Snake River, prevent the passage of any unutilized water beyond the borders of the Territory.

Summary of irrigation development by districts.

District.	Total No. of recorded ditches.	Total length as stated.	No. of claims, with statement of length omitted.	Total capacity as given.	No. of ditch claims, omitting statement of capacity.	Total acreage watered as given.	No. of ditch claims, omitting statement of acreage.

IRRIGATION, PUBLIC LANDS, AND CANAL CONSTRUCTION.

No. II.

[This paper was read by Engineer Meade to the committee.]

As the official head of the irrigation systems of this Territory, I have the honor to present this statement describing its agricultural resources and possibilities by the aid of irrigation, the character and extent of the work already performed, and of explaining the views of our people as to the measures necessary to secure the full utilization of our water supply in reclaiming the unoccupied arid lands.

Among the arid Commonwealths Wyoming stands the third in the extent of her irrigated land, while in the excellence of her laws and the legislative measures for the promotion of this interest she deserves even a higher rank. Although the youngest of the Territories and suffering greatly from the lack of railroad facilities, particularly between the agricultural districts of the north and the mines in the south, only California and Colorado surpass her in the mileage of canals or the area of land watered therefrom. This rapid development has been due to two causes, the first being the exceptional natural advantages of the Territory as a grazing region, and which at an early date made the raising of cattle its most important industry. With the cattle man to open the way and make settlement possible, the farmer soon followed. And as the necessity for winter feeding became apparent, the profits of the cattle business were invested in the construction of ditches to enable such food supplies to be grown.

The second reason is found in the abundance of the water supply and the ease and cheapness with which the waters of the streams can be diverted. The description of these streams and the nature of the works already built to divert their waters is given in Appendix A, attached to this report. It will be sufficient here to state that the principal streams have their sources in mountains of sufficient elevation and extent to make them abundant accumulators and conservators of the needed moisture, and that from these natural reservoirs these fruitful arteries of our agricultural life penetrate every section of our broad area. No other arid State or Territory equals this in the number of its streams whose waters can be diverted or in the uniformity of their distribution over its entire area. The location of the natural water-courses is such that if they carried sufficient volume of water all the lands could be easily and cheaply watered, while, on the other hand, there is but little land which would not be made productive if the water could be had. Hence it is that no subject has to this Commonwealth the same ultimate importance as the proper conservation and use of all water that falls on its surface.

The solution of the problem of how best to accomplish this involves an inquiry into two matters, first, the proper distribution of the water over the land, and, second, the conservation and storage of the flood water and the water running to waste in the non-irrigating season. In considering these questions regard must be had of the works already built and of the methods adopted and in practice among the farmers of the Territory, since no methods can be successfully carried out which do not accord in a measure with the views and interests of those already in the work. While the area irrigated is far less than that awaiting reclamation it is too important to be lost sight of in any plans for future work. The ditches now in operation and the acres of land which they water have involved the outlay of many millions of dollars of the earnings of our citizens. When they began their work the success of agriculture by irrigation was problematic. It was through their confidence and energy that the country now understands and appreciates its value and importance, and it is their efforts which has given the arid region whatever value it has. Hence, no action should be sanctioned which does not promise to promote the financial success and prosperity of the works already constructed. While the northern part of the Territory has outstripped all other portions in the extent and value of its irrigated lands, in all sections the construction of ditches has reached a surprising degree of importance and there is no portion in which the agricultural lands do not form an important part of the natural resources.

Much of the work done is faulty, resulting in heavy and unnecessary expenses for operation and maintenance and great loss of water in distribution. We have too many small canals watering the bottoms and not enough large canals watering the uplands. Our methods and system need reforming to prevent this in the future work. It is the result in part of the lack of means and experience on the part of the pioneer ditch-builders, but very largely of late years of the unfortunate circumstances of our land laws being wholly unsuited to the conditions of this region, and of their administration being in the hands of men ignorant of these facts.

It is a well-settled principle that lessening the number of ditches by building large high level canals results in both economy of water and saving in operating expense. It also, as a rule, secures the watering of more fertile and productive land. To build large ditches, however, requires either a community of effort on the part of the farmers owning the land or the introduction of capital to build canals to rent water. The first plan has seldom been successfully pursued. The length of time required to prepare for and complete the construction of a large canal, and the fact that farmers can produce nothing to support themselves or their families until this is accomplished, has prevented its successful adoption. Hence the majority of the large irrigation works have been built as common carriers of water, this plan seeming to best meet our conditions and needs. There is no objection so far as I am aware and many things in favor of this plan, provided the canals are properly built and furnish water at a reasonable rental. They are a necessary and valuable feature of our irrigation development, and we should have such laws as will make the investment a safe one and secure their construction under such conditions as will enable them to furnish water to farmers at a minimum cost.

Unfortunately, however, the building of large canals to furnish water to the settlers on the public lands gives rise to a condition of affairs which, while well understood here, is apparently not appreciated elsewhere. Before the canal is built these lands are valuable only for grazing purposes, which value in most cases does not exceed 50 cents per acre. The construction of the canal, however, carries with it the assurance of their reclamation, enhancing their value to that of farming land, so that without the purchase of a water right or without the owner of these lands having in any way contributed to their improvement their value is increased at a low estimate from $5 to $15 per acre. This unearned increment is due entirely to the expenditure and efforts of the ditch company which expects its return from the rentals of water to the settlers on the lands thus made susceptible of cultivation. If therefore all filings under the ditch were made by persons expecting to become cultivators of the soil, and who would at once become users of the water, no harm would ensue. Unfortunately, however, our land laws make possible an entirely different result. The increase in value resulting from the construction of the ditch is a rich field for the speculator. Parties having no desire or intention of becoming farmers can through the pre-emption law, the homestead law, and the timber-culture law obtain possession of 480 acres of this land without having to rent a gallon of water from the ditch company or in any way contributing to its maintenance or advantage. By the expenditure of 25 cents per acre they can in the same way obtain a three years' option on 640 acres additional by desert entry. Thus it is that over a thousand acres of land are withdrawn from honest settlement and the speculator or entryman is in a position to blackmail the ditch company, as it is only by its buying him out and disposing of these lands to bona fide farmers that it can derive any income from the water supply. This situation of affairs has made it impossible in this Territory to construct large ditches simply as common carriers of water. The success of the enterprise makes it necessary that the lands should at once be brought under cultivation, and to accomplish this there must be some control over their settlement. This neither the ditch company nor the Territorial authorities can attempt at present.

There are in the Territory a number of important canals built to rent water and all have suffered from the difficulty of securing a prompt settlement of the land reclaimed. Some of these have endeavored to protect their investment by securing this control of the lands, the most important instance of this being the Wyoming Development Company, its field of operation lying about 90 miles north of this city. It began originally with the intention of furnishing water to the farmers, but it soon became manifest that unless they could control the settlement of the lands that the only parties to derive any benefit from their efforts would be the parties filing on the land, and that if the lands were to be actually made productive they must take steps to control their settlement. This was done and in this work and in the construction of their canal about $500,000 was expended. The enterprise has been in every respect a most praiseworthy one. Over 50,000 acres of land have been watered by one of the best systems of canals to be found anywhere in the arid regions, yet owing to the lack of appreciation of the real situation of affairs and of the necessities of this region these lands lie idle and unproductive in the hands of the Government, and the projectors of one of the best enterprises yet inaugurated in this Territory have been put to the expense and annoyance of maintaining for five years a system of costly and unproductive irrigation works. The unfortunate outcome of this company's operation has been in the widest sense a disaster to the Territory. Its example is a menace and a virtual barrier to the inauguration of other enterprises of special magnitude, and has resulted in a return to the original practice of building small ditches, where each individual could manage and control his own claim, the opportunities presented for the diverting of water making possible an extraordinary development of this nature. The evil consequences of this state of affairs are many. It creates a system difficult to control, expensive to operate, and wasteful of water. Not only that, but many of our best lands can only be reclaimed through the medium of extensive and costly works. If during the past five years we could have had a system of land laws that would have enabled ditch companies to have secured actual settlers on the lands reclaimed, the number of important irrigation works and the extent and wealth of the irrigated territory would be fourfold that which exists.

A proper utilization, however, makes it desirable that additional changes, besides reforming our land laws, should at once be made. Since the area of land which can be irrigated is greater than the available volume of water, it is desirable that our irrigation works should be so located as to serve the best of these lands, and that the water supply should be so distributed as to insure the utmost economy in its use. To do this it is necessary that a careful examination of the streams should be made in advance of irrigation construction, and that these works should be built in accordance with an intelligent system and plan. It is further to the interest of the State that this should be done, since it is charged with the responsibility and expense of supervising these works after they are built and with the division of the water among the various claimants. Under the haphazard system which has heretofore prevailed, where there has been no limitation or supervision as to the number, location, and character of the works for diverting water, it becomes a practical impossibility to secure a just or satisfactory distribution of the water supply in a time of scarcity.

The ill results of this policy become more pronounced the longer it is pursued. They are more notorious in Colorado than with us, and will be felt here in ten years far more than at present. It is a counterpart of the old land system, or lack of system, which formerly prevailed in this country and in some of the Eastern and Southern States, where each settler blazed out his domain according to his inclination, regardless of the boundaries or rights of his neighbors. The litigation and ill-feeling which followed as a legacy of this practice in Kentucky and other States promises to be repeated in our water-right troubles if some more enlightened policy be not adopted. That our system is what it is is not due to the lack of appreciation of its defects on the part of our people or the want of the knowledge of a remedy. It is a system forced upon us by necessity, not choice. A Territory sparsely settled, with its resources undeveloped, was not in a situation to undertake any systematic public improvement or investigations, nor can we accomplish anything satisfactory towards this end with the public lands owned and controlled by the General Government. It is useless to make any investigation or examination as to the proper location of irrigation works while no control can be exercised over the settlement of the land.

The most satisfactory remedy for this state of affairs, and, in my judgment, the only efficient one, is for Congress to grant to each State of the arid region, or to each Territory upon its becoming a State, all the irrigable lands within its borders held by the General Government, such States to be charged with the supervision of their reclamation and with their disposal to actual settlers.

The reasons for asking this donation were stated in a letter prepared by a committee appointed at a conference held in this city in July last, and I can do no better than repeat them here:

"First. The reclamation of the lands of this region lays upon the people engaged and upon our local or State government requirements and expenses not encountered by the pioneer of the humid portion of the country. Not only does the construction of ditches and other distributing works add greatly to the first cost of a farm, but with their multiplication comes the necessity of the State assuming control of the distribution of the water supply, and its failure to do so leads inevitably to expensive litigation or to personal controversies which impair both the success and the growth of our agriculture. A further incentive to prompt action is the fact that the area of land susceptible of reclamation exceeds the amount of water supply. The water, therefore, possesses a greater value than the land, and on its economical distribution rests the limit of our future agricultural wealth. It is of the utmost importance, therefore, that no wasteful or improper diversions be permitted, and that the State should control the appropriations of water as well as its subsequent division among the various claimants. The expense of this work must of necessity be heavy. In Wyoming there are already two thousand five hundred ditches drawing their supplies from four hundred water-courses, and this work is yet in its infancy. In Colorado, with its greater advancement, the single work of regulating the division of the water supply requires the employment by the State of nearly one hundred men. This regulation is a necessity not to be avoided, but the preliminary examination of our streams and an efficient supervision of the construction of works to divert the water therefrom is of equal importance to our future welfare. In our present condition it will, however, be a practical impossibility for many of the States and Territories to provide means for this work by taxation; but the funds for its prosecution can be easily provided for in the disposal of the lands whose donation is asked.

"Second. Our experience during the past five years has shown the evils growing out of the control of the land being under one authority and the water under another.

"If this Territory could during the past five years have controlled the disposal of the irrigable lands within its borders, it could, while disposing of it to actual settlers only, have afforded such protection to canal companies as would have given our agriculture four times its present importance, and more than doubled our population. Instead of this there have been repeated instances where arbitrary and unreasonable rulings have subjected our people to heavy and wholly unnecessary expense, and to cause the whole land policy to be regarded as oppressive. It was, however, the inevitable result of land laws wholly unsuited to the needs of irrigation, and of their enforcement by officials in Washington whose experience had not prepared them to deal with the conditions which exist here.

"It is also impossible for Congress to pass a general law which will operate with equal justice and success on the arid belt as a whole. The conditions differ in the different sections as do our water laws. Wyoming differs from Utah, and Arizona from Montana or Idaho. The people of each section are the best calculated to determine the system best suited to their needs and should be given the means of carrying it into effect.

"Third. The results already achieved are a sufficient guaranty of what can be accomplished under favorable circumstances. Our legislation as to water has, on the whole, been wise, but it can never have the stability or success which would come with the control of both water and land. Our engineering works have elicited the praise of experts from other irrigated countries for both their economy of construction and adaptation to their use. At present the practical knowledge of the subject is almost wholly confined to those engaged in the work. The information gained through the labors and investigations of the geological survey can be utilized by local legislatures, while by placing the responsibility for this work upon our people a great impulse will be given to the diffusion of intelligence on the subject and to local pride in the character of our irrigation works. It will put the solution of this problem in the hands of the people best informed on the subject and most interested in its success.

"We will say further, that our people are afraid of the proposed withdrawal of the irrigable lands from settlement or the placing of the construction and control of our irrigation works under the charge of the National Government; the reason being in both cases that the delay and uncertainty which would be inseparable from such action would be disastrous. While the passage of laws to encourage individuals or companies to reclaim large bodies of arid lands would most speedily accomplish the desired end, namely, reclamation and settlement of the arid regions, yet public sentiment seems to be so adverse to this plan that we feel that it is scarcely worth our while to advance it."

The dangers attendant upon national legislation is shown in that clause of the law creating the irrigation survey which provides for the repeal of all land laws except the homestead act. This change has met with the disapproval of all persons acquainted with the situation in this Territory. To limit the acquirement of title to the public lands to the provisions of the homestead act would be disastrous restriction on settlement and there is no valid reason for its adoption. It offers no aid toward the construction of better works or the more economical diversion of water, the most important consideration connected with the whole subject. In this respect the desert land law was the best ever enacted, if it had been liberally construed or if the rulings of the land office had been uniform as to its meaning. The difficulty has been that the changes in the rulings have been of so radical a character as to practically constitute new legislation and to cause much hardship and expense to those honestly endeavoring to comply with the law. So onerous have been some of the restrictions that it has seemed as though the authorities regarded every claimant of the public lands as an object of suspicion who was guilty until proven innocent. It is time that more sensible and just conception prevailed. Every settler on these lands which in their present condition have no agricultural value, and who reclaims them and makes them productive, is a benefactor of the whole country and should receive the most liberal treatment. Instead, however, after having expended from $5 to $15 per acre in bringing the water on his land and preparing it for irrigation, he is compelled to pay the same price therefor that the settler on the broad prairies of Iowa and Kansas paid for land already prepared for the plow.

The commonwealths who are charged with the duty of guarding the public welfare should be aided in their efforts. Every consideration which justified and secured the donation of the swamp lands to the States of the humid region applies with greater force to the advisability of a similar donation of the arid lands to the several States and Territories interested. Not only are our local governments charged with heavy duties and responsibilities which none of the humid States had to confront, but the settlers who come here to engage in farming undertake the practice of an art whose mastery is both complicated and difficult, and of which they have had no previous experience. Our climatical conditions are exceptional, making much of our agriculture and experiment, and making certain that we are far from pursuing the best methods or that we are achieving anything like the results which are possible. The local government should aid private effort by conducting experiments to determine the best methods, and by disseminating information which will enable new comers to obtain their knowledge of the subject by some less difficult and costly road than that of experience. The success of irrigated agriculture enormously increases the value of the arid domain, and will be an important contributor to our national wealth and prosperity. The best results can only be secured through the nation's aid. I trust it may be generously extended.

TERRITORIAL ENGINEER'S REPORT TO THE GOVERNOR OF WYOMING.

[Copy with the committee, by Engineer Mead.]

No. III.

The work of this department may, for convenience, be divided into four classes, as follows:

(1) Preparation of instructions for water commissioners to enable them to perform their duties in accordance with the court decrees determining priorities.

(2) The gauging of canals and preparation of tables showing discharges of the various ditches; these tables to be furnished to both the commissioner and ditch-owner.

(3) The recording of decrees and recording and calculation of engineer's certificates as required by law.

(4) The gauging of streams, examination of reservoir sites, collection of data showing the location and extent of our irrigation resources, and such other work as will extend our knowledge of irrigation and advance our agricultural interests.

A beginning has been made in the work of each of these divisions. Three decrees have been rendered in District No. 1 and one in District No. 8, all of which have been recorded, and the proper instructions have been given the commissioners.

No gauging of ditches have as yet been made, but plans and instructions for the construction of measuring flumes have been prepared and furnished to the various ditch-owners, and the work of gauging these will be the first work to engage my time next spring.

A part of the present irrigating season was given to the gauging of streams and the examination of irrigation work. The tour of investigation began in May and ended in August, and included a large part of Laramie, Albany, Johnson, and Sheridan Counties, together with visits to Sweetwater and Uinta Counties.

Without attempting a detailed report of this examination it may be well to mention some of the conclusions to which it led.

The soil wherever examined is fertile, and wherever irrigated becomes exceptionally productive. Grasses and the hardier grains and vegetables do well in all parts of the Territory, but in some localities the elevation is too great to successfully grow corn and some kinds of vegetables. The eastern and northern portions of the Territory are able to produce nearly all kinds of fruits and vegetables grown in temperate regions, the lower elevation of the northern part (3,500 feet at Sheridan) compensating for the difference in latitude.

A distinctive feature of Wyoming's irrigation is that it outstrips all the States and Territories of the arid region in the number of its streams available for irrigation. The valleys bordering most streams are narrow, varying in width from one-half to 5 miles, and the uplands between these valleys too high to be watered, and which must remain as grazing land. This contiguity of large tracts of grazing land to that devoted to farming, affording as it does free summer pasturage for the farmer's stock, is a material advantage and is destined to increase the profits of the farmer and greatly enhance the value of the irrigated lands.

The counties of Albany and Laramie furnish the best examples of ditch building, the largest and best constructed ditches being found there. The irrigation works of these two counties also must nearly utilize the waters of their streams, on a majority of which the aggregate capacity of the ditches exceeds the average discharge of the stream during the irrigating season, and the further extension of the irrigated territory can only be accomplished through the construction of reservoirs to store up the surplus water of the spring floods. The fertility of these lands, and their nearness to a market for their products, make it extremely desirable that such works should be built, but their cost puts the work out of the field of individual effort.

In nearly every part of the Territory visited there are favorable locations for the investment of capital in the construction of irrigation works of too great magnitude for farmers to attempt; these no doubt will be utilized in the near future. It will be seen, however, in the statistics given further on in this report, that if the lands in this territory now under ditches, and susceptible of being irrigated, were being cultivated, Wyoming would take rank as an important agricultural commonwealth. At present, not one-twentieth part of this land has ever been tilled, the reason being found in the lack of railway facilities for transporting the produce of the farms to market, and in the lack of means on the part of the farmers to bring their lands under cultivation. Construction of laterals, and other work necessary to reclaim arid lands, entail a heavy burden of expense the first few years. In no part of this country, however, can agriculture be pursued with more success and profit than in this Territory, and the present condition of affairs must soon disappear.

DITCH STATISTICS.

One of the first needs which impressed itself upon me in the discharge of my duties was the almost indispensable necessity for having in this office a record of the ditches already built, together with the data showing their size, location, and data of construction. This information could only be had through an examination of the "claims to water" recorded in the offices of the various county clerks throughout the Territory. To properly examine these records, and make the necessary abstracts from them, required the expenditure of considerable time, but the importance of the record seemed to justify its being undertaken.

Below is given a tabular summary of the irrigation development of the Territory as far as the records have been completed; the statistics for Carbon and Fremont Counties having not as yet been compiled.

In preparing this summary, wherever the length, capacity or acreage of a ditch was omitted in the statement of claims, no attempt was made to supply the omission, nor has any addition been made to the totals on account of such omissions, while the tendency of statements is to exceed the actual facts, the fact that 20 per cent. of the statements failed to give the acreage and about 10 per cent. omitted giving the length will make the totals rather below than above the truth.

When the statistics of Carbon and Fremont counties are added to those below, it will increase the acreage under the ditch, and capable of being irrigated, to over 1,500,000 acres.

Table showing extent of irrigation in Wyoming.

County.	No. of ditches recorded.	No. of ditches omitting statement of length.	Length as given.	No. of ditches with statement of capacity omitted.	Capacity of those given.	No. of ditches with statement of acreage omitted.	Total acreage of those given.
					Cu. ft. pr. sec.		
Albany	288	27	496.32	45	6,024.99	62	345,341
Crook	115	46	198.90	40	562.17	64	58,937
Johnson*	434	33	729.86	55	9,117.30	48	303,300
Laramie†	590	30	1,122.38	42	4,300.00	79	390,803
Sweetwater‡	21	4	179.3	15	....	12	4,350
Uintah	270	27	482.2	95	1,202.87	82	107,452
Carbon §	....	....	....	....	....	....	....
Fremont §	....	....	....	....	....	....	....
Total	1,718	167	3,208.96	292	21,207.33	347	1,210.143

* Includes Sheridan County. † Includes Converse. ‡ Statistics very incomplete. § Not completed.

In the examination of these statements of claims it was found that in many of them essential facts were omitted and immaterial and irrelevant matter included, thus lessening the value of the record and greatly increasing the labor of examining it.

Believing that these incomplete statements were due to ignorance of what our law required, rather than to carelessness or neglect, and realizing that these imperfect records were likely to prove a fruitful field for controversies and expensive litigation, I took what steps lay in my power to secure the filing of complete statements in the future, by preparing a standard form of statement, which was mailed to the various county clerks with the following letter:

To the appropriators of water:

"An examination of a large part of the claims to water, now on file in the offices of the various county clerks of the Territory, has disclosed the fact that a wide diversity exists in the character of the statements contained in these claims.

"This is shown in the different orders in which the essential facts are arranged; in the use of the different units to designate the volume of water claimed, and in the various forms in which the dimensions and grades of ditches are expressed. This lack of uniformity proves a source of serious annoyance and perplexity to those who have occasion to examine the records. To reduce these varying units to a common standard, which becomes necessary whenever any use is made of these records, is a work involving considerable time and labor, which could be avoided by the use of a standard form in the original statements.

"Another, and more serious, defect which has been observed in these claims, is the failure of any to state all the facts necessary to the determination of the claimant's rights or his protection in them. These omissions include nearly every portion of a complete claim, but the most serious and numerous are the failures to state fully or properly the dimensions of the ditch or the volume of water claimed. The unit employed for the latter is often so indefinite as to be practically valueless. Claims for 'square inches,' 'agricultural inches,' 'California inches,' or 'miners inches' are decidedly out of place in this Territory, where the law recognizes no unit except the cubic foot per second.

"These incomplete statements are destined sooner or later to prove a source of serious annoyance, if not of expense, to the parties filing them, since, whereever an adjudication is had, the missing facts will have to be supplied.

"As an aid to secure the proper filing of these claims in the future, and the consequent protection of the rights and interests of claimants, I have prepared a standard form of claims, the use of which throughout the territory is strongly urged. The advantages of uniformity and systems to be secured by this means are so many and important that it is hoped that this request will, in all cases, be complied with.

"Copies of this form have been furnished to all the county clerks and county surveyors of this Territory, who will doubtless make arrangements for their being readily obtained."

All the county clerks have co-operated with me in this matter with a resulting gain to the public in the convenience, system, and reliability of our water records, which only time will enable us to properly appreciate.

The volunteer weather service has also been established in connection with this office, the signal service loaning the necessary instruments. Five stations have been thus far established, each in an agricultural district, at which observations of temperature and rainfall are being made.

Before closing this report I wish to call attention to one or two matters which seriously embarass the working of our irrigation system, and which will require the early attention of our lawmakers.

The irrigation laws of this territory, taken as a whole, are perhaps in advance of those of any other State or Territory of the arid region. All irrigation legislation in this country has, however, been tentative and fragmentary. There has been no attempt to frame a complete irrigation code, but only to enact such laws as the immediate necessities of the irrigation interests seemed to demand; the result of which, owing to the rapid growth of the irrigation interest, is that legislation calculated for its regulation and protection has not kept pace with the conditions developed by its growth.

While the evils resulting from this state of affairs have not been so serious or apparent here as in Colorado or California, our present laws are in some respects wholly inadequate, and will need to be supplemented by additional legislation.

Over two thousand ditches have already been completed in this Territory, and have their claims to water on file in the offices of the various county clerks. These ditches water an area equal in extent to the whole of the irrigated district of France and Spain combined, and one half that of Italy. They are distributed throughout a region almost as large as the whole of New England; yet, at the time I entered upon the performance of my duties, the service of only one man was available for the work of dividing the water supply in accordance with their claims, and his time of service was limited to fifty days.

The scarcity of water which prevailed in many locations made the need of proper supervision unusually urgent.

Requests from prior appropriators, who were unable to secure their rights, came from all parts of the Territory asking for the service of water commissioners to regulate the division of the water supply. As there were no commissioners to act, and their authority to act in such cases was doubtful, nothing could be done. The need of some action was, however, so apparent that I referred the matter to the attorney-general, asking if there was any authority by which the water commissioner could divide the water of streams whose ditch rights had not been adjudicated. I append below an abstract from his reply.

"I have carefully examined the Revised Statutes of Wyoming, as well as the late laws enacted, and I find nothing either directly or by implication on our statute books which will give you as Territorial engineer authority to determine the priorities on any streams of this Territory, nor is there anything in the laws that would permit the water commissioner to divide the waters of any stream whose priorities have not been determined as directed by law, nor can he perform his duties previous to receiving the instructions set forth in section 9 above referred to."

This law, therefore, as it now stands, limits the work of water commissioners to those ditches whose priorities have been determined by the court. The right of less than 5 per cent. of the ditches of this Territory have been so determined, and to leave the rights and interests of the remaining 95 per cent. without protection or regulation until the courts can attend to them, will inevitably give rise to bitterness of feeling and to conflicts which will not only seriously retard our agricultural progress, but will for the next quarter of a century embarrass the introduction of proper supervision.

As ditches are now being built faster than their rights are being determined, it is manifest that some provisional measure should be adopted to secure proper regulations in the interregnum. The plan which would best subserve this purpose would be, I think, for the Territorial engineer to be authorized to instruct the water commissioners to divide water on all streams where regulation is necessary, the engineer basing his instructions as to the manner of division on the statement of claims now on file.

It is not designed that this should do away with the final settlement of the rights of claimants by the court. There should be the right of appeal to the court from the engineer's decision at all times, and the final decree of priorities should be rendered by the same authority. What is needed, and what it is believed the proposed step will accomplish, is the protection of the rights and interests of the pioneers of our agriculture until such time as the courts can properly attend to these matters.

In fact it is desirable in many cases that the determination of priorities should be deferred until the era of rapid ditch construction has ended, in order that all the ditches of a stream may be included in the adjudication, and that a second or third consideration of the matter, due to subsequent ditch construction, be avoided. Another advantage of delay in adjudication will be that farmers will be better informed as to the nature of the laws and the importance of having their interests properly represented before the court renders the decree. That this is not now the case is shown in two of the decrees already rendered, where a large number of ditches already built were not represented in the proceedings nor included in the decrees.

Attention has been called to the defect in the present method of filing claims to water and the means employed to improve them. I am convinced, however, that the only effectual remedy lies in change from our present system which will provide for the examination of every claim before the filing. The tabular statement in a preceding part of this report illustrates the large number of omissions of essential facts exhibited in these statements. It does not, however, exhibit the imperfections of statement nor the irrelevant matter which encumbers so many and makes their examination or utilization so difficult.

While writing this report I was told by a farmer that in the filing of his claim he was obliged to make three visits to the county seat, a distance of 40 miles, and to pay for the recording of three statements before a correct record was secured. I have heard so many statements of the same character and have seen enough duplicate records to convince me that some radical change is necessary.

The remedy I would suggest would be—

First. To make it the duty of the Territorial engineer to prepare a standard form of water claim which shall embody the requirements of our present law; this form to be used by all persons filing claims to water.

Second. Every person wishing to file a statement of claim shall first forward a copy of such statement to the Territorial engineer, whose duty it shall be to examine this claim. If correct, he shall approve it and record it in his office and return the statement with his approval to the party making the claim, who shall then have recorded the approved claim in the office of the county clerk. If the statement forwarded to the engineer is imperfect or incomplete, it shall be his duty to return it for correction, designating the errors or omissions, which when remedied, shall be returned for examination as before, and if approved, to be recorded and returned as before stated.

The advantages which would accrue from this change would be, the engineer's office would at all times have a complete record of the location and progress of ditch building, and the public a source of information of the extent and character of our irrigation development. It would greatly improve the character of the record, making it more convenient to examine and preventing the filing of worthless statements. It would, by the correction of imperfect statements, serve as an educator, showing the ditch-owners the purpose and requirements of the law and would protect him from any annoyance and expense incident to the filing of such imperfect statements.

In calling attention to these features of our irrigation laws that need legislative revision, I have been more remindful of the demands of the future than of the disadvantages of the present. The subject of comprehensive irrigation legislation will be one of the most important to engage the attention of our next general assembly. The future development of our agricultural interests is certain to be rapid and important. As it is, with our irrigation system scarcely established, we have enough land under ditch and ready for the plow to make twenty thousand 80-acre farms, and to engage the efforts of a purely agricultural population of more than twice the number of all the people now in the Territory. Many of these ditches have been built under exceptionally unfavorable conditions; the best watered and most extensive agricultural districts being in the central and northern portions of the Territory, while, until within the past two years, all the materials and implements required in the construction of ditches, together with a large part of the provision for men and teams had to be hauled from the stations of the Union Pacific which traverses the southern border.

The transportation by wagon of all this material for distances varying from 100 to 300 miles almost doubled the cost of the work and materially lessened the prospect of profitable returns. So also the remoteness of a staple market and the difficulty and expense of obtaining the conveniences of life have been a serious drawback to many of our pioneer farmers. Where it required a three weeks journey to buy a plow, as it did until recently, in many cases there was not much plowing done.

The Territory still suffers from the lack of adequate railway facilities. There is a surplus of agricultural products in the north for which there is a ready market and good prices in the south. The completion of the railroads projected to bring these sections together will result in increased prosperity for both. It will encourage the cultivation of an increased acreage, and will make accessible to the capitalists a country now practically unknown.

In the counties of Johnson and Sheridan alone, the surplus water of the streams gauged by me this season would irrigate 500,000 acres, and I am reliably informed that there is double that extent of land susceptible of being watered. Were it necessary other illustrations of the same character could be given. It is certain, however, that agriculture is destined to be one of the most important, as it is one of the most stable, of the Territory's material interests and the perfection of the methods and practices on which its success and progress so largely depends should receive the most careful consideration.

ADDENDA TO TERRITORIAL REPORTS.

Attention is called to the table in the report giving the statistics of our irrigation development. Since that was written the corresponding statistics for Fremont and Carbon Counties have been compiled, and the result which follows more than justifies the statement in the report that there is land enough under ditches and susceptible of being irrigated to make twenty thousand 80-acre farms. The statistics are below the actual development, as many ditches have been built since the records were began and are not included, and a larger number have never been recorded. An addition of 25 per cent. to the totals would probably be nearer the actual situation.

Abstract from ditch records of Fremont and Carbon Counties.

	No. of ditches.	Length.	Capacity per second.	Acreage.
		Miles.	*Cubic feet.*	
Carbon Company	304	421.60	4,451.64	1,084.44
Fremont Company	181	226.27	....	441.81

This makes the totals for the Territory, so far as completed, as follows:

Total mileage	3,852.83
Total acreage under ditch	1,413,404

Four-fifths of these ditches have been completed within the past five years. It is probably the most rapid development yet recorded in any State or Territory, and when considered in connection with our unfavorable conditions incident to lack of railroad facilities, and to the fact that the present land laws are not suited to the conditions of the arid region and their technical enforcement has oftentimes caused great hardship and unnecessary expense to the pioneer farmers, it furnishes a gratifying evidence of the superior inducements of our agriculture and the facilities here presented for the economical construction of ditches. Nearly the whole of this is the result of the efforts and expenditures of the farmers and cattlemen of the Territory.

Water district No. 8.—Claims to water as taken from the records of Fremont County.

Name of stream.	Name of ditch.	Dimensions.					Grade per mile.	Amount claimed per second.	Date.	Number of acres under ditch.

† Claim 1,800 inches.

No. IV.

EVIDENCE PREPARED THROUGH CIRCULAR LETTER TO CITIZENS.

CHEYENNE, *August* 17, 1889.

Mr. ——— ———:

DEAR SIR: I desire to place before the Senate Committee on Irrigation a correct and impartial statement of our present agricultural development, together with the circumstances and conditions under which it has been accomplished.

As an aid in doing this I wish to obtain the statements of a large number of farmers in different parts of the Territory of the difficulties and expense attending their efforts to reclaim the desert and the results which they have obtained.

I mail you with this a list of questions which I trust you can find time to answer. I am particularly desirous of learning your experience under our present land laws and your views as to what changes thereto are needed. The evidence thus collected will be arranged and presented to the committee.

The modifications of our land laws effected by the last Congress and the probability of further action by the coming one makes it of the highest importance that our wishes and necessities be properly presented and understood.

I trust I shall have your aid and co-operation to this end.

Respectfully,

ELWOOD MEAD,
Territorial Engineer.

TERRITORY OF WYOMING, ENGINEER'S OFFICE,
Cheyenne, September 22, 1889.

I hereby certify that the accompanying letter, asking for testimony to be used before the Senate committee, and the responses thereto, are a full, true, and exact copy of the originals now on file in this office.

ELWOOD MEAD,
Territorial Engineer.

Name, ANDREW GILCHRIST; county, Laramie; post-office, Cheyenne.

1. How long have you resided in the Territory?—About fifteen years.

2. In what year did you begin farming?—In 1877.

3. How much land have you under ditch?—Personally, about 2,000 acres.

4. If obtained from the Government, state the filings which were made.—Lands entered under the desert, pre-emption, and homestead acts, and lands purchased from the Union Pacific Railroad.

5. How many acres are now under cultivation?—About 2,000 acres.

6. By what ditch or ditches is it watered?—By nine ditches, named "Gilchrist No. 1 to No. 9."

7. From what stream or streams is water taken?—South, Middle, and North Crow Creeks.

8. Give history of construction of ditch:

(*a*) Names of owners.—Andrew Gilchrist and Mary Gilchrist.

(*b*) Date begun and time occupied in building.—Began April, 1877; the last ditch was completed in 1887.

(*c*) Dimensions.—The nine ditches are of various dimensions.

(*d*) How many acres does it water?—The nine ditches water about 2,000 acres.

(*e*) What was the cost of construction?—About $10,000 for the nine ditches.

(*f*) What is the cost per year for management and repairs?—About $200.

9. Do you buy or sell water; if so, state price paid or received.—I neither sell nor buy.

10. Have you all the water needed; if not, state the reason.—No, not every year. In dry seasons there being but little snow in the hills the supply of water in the creeks is therefore limited, and the city of Cheyenne claims first appropriation for domestic purposes.

11. What is the usual cost of bringing wild land under cultivation? This to include plowing, grubbing sage brush, fencing, etc.—About $10 per acre.

12. How many years' cultivation are required to bring wild land into proper condition for farming?—From two to three years.

13. What did it cost you to prove up and obtain title to your land, and what was the length of time required? If any difficulties were encountered, state what they were.—Cost from $8 to $10 per acre. Difficulties encountered in obtaining title from

the Government are many, principally on account of the tardy action of the General Land Office after final proof has been made.

14. What has your cultivated land cost you per acre? This to include cost of proving-up, cost of ditches and laterals, expense of preparing land for cultivation, fencing, and all permanent improvements.—See answers to previous questions.

15. What is its present market value per acre?—Probably it could not be sold for more than $10 per acre, on an average.

16. Can you raise crops without irrigation? If so, state what they are and yields obtained.—No crop can be raised without irrigation.

17. Do you think the present land laws are adapted to the conditions of this Territory? If not, what changes would you suggest?—I do not think the present land laws are well adapted to this Territory. My opinion is that if the land, like the water in the streams, was under the control of the Territory or State much more satisfactory results would be obtained, as under the present existing conditions they do not work harmoniously, and large irrigating enterprises suffer a great deal of injustice, and the progress of the settlement of the lands and the development of the resources of the Territory are retarded.

18. What should be done with grazing land which cannot be irrigated? What is its value per acre?—I would suggest that the lands of that nature should be sold to parties having irrigable lands contiguous thereto for grazing purposes. I estimate their value at from 25 cents to $1.50 per acre, according to their grazing qualities, location, and water facilities for stock.

19. How do you regard the withdrawal of all public land from settlement during the irrigation survey?—I regard that such action would be detrimental to the progress of the Territory, as it would practically prevent the settlement of all agricultural lands and put a stop to further irrigation enterprises.

20. Do you favor the donation of all irrigable public land to the Territory?—I would recommend that all agricultural and grazing lands be donated by the General Government to the Territory.

Name, **JOHN A. FISHER**; county, Albany; post-office, Laramie City.

1. How long have you resided in the Territory?—Nineteen years.

2. In what year did you begin farming?—I am not farming as yet.

3. How much land have you under ditch?—About 1,200 acres.

4. If obtained from the Government, state the filings which were made.—One-half section desert, part of a school section, and one-half section railroad land.

5. How many acres are now under cultivation?—[See answer to question 2 above.]

6. By what ditch or ditches is it watered?—By the Fisher ditch.

7. From what stream or streams is water taken?—From the Big Laramie River.

8. Give history of construction of ditch:

(*a*) Names of owners?—John A. Fisher.

(*b*) Date begun and time occupied in building?—It was begun in the month of May, 1884.

(*c*) Dimensions: length, miles, 75; depth, 2 feet; width, 9 feet.

(*d*) How many acres does it water?—Twelve hundred acres.

(*e*) What was the cost of construction?—About $5,000.

(*f*) What is the cost per year for management and repairs?—About $50.

9. Do you buy or sell water; if so, state price paid or received.—I do not.

10. Have you all the water needed; if not, state the reason.—I have.

11. What is the usual cost of bringing wild land under cultivation? This to include plowing, grubbing sage brush, fencing, etc.—Don't know as yet.

12. How many years' cultivation are required to bring wild land into proper condition for farming?—I can't tell.

13. What did it cost you to prove up and obtain title to your land and what was the length of time required? If any difficulties were encountered, state what they were.—I have not proved up as yet.

14. What has your cultivated land cost you per acre? This is to include cost of proving up, cost of ditches and laterals, expense of preparing land for cultivation, fencing, and all permanent improvements.—[No answer.]

15. What is its present market value per acre?—[No answer.]

16. Can you raise crops without irrigation? If so, state what they are and yields obtained.—No.

17. Do you think the present land laws are adapted to the conditions of this Territory? If not, what changes would you suggest?—[No answer.]

18. What should be done with grazing land which cannot be irrigated? What is its value per acre?—[No answer.]

19. How do you regard the withdrawal of all public land from settlement during the irrigation survey?—I do not believe in it.

20. Do you favor the donation of all irrigable public land to the Territory?—I do.

Name, **Luke Voorhees**; county, Laramie; post-office, Cheyenne.

1. How long have you resided in the Territory?—Fifteen years.
2. In what year did you begin farming?—1878 in a small way.
3. How much land have you under ditch?—About 4,000 acres.
4. If obtained from the Government, state the filings which were made.—Luke Voorhees, desert 640, October 10, 1880; George M. Drake, desert, September 15, 1880; George D. Jenks, desert 280, May 24, 1880; Florence L. Voorhees, desert 600, November 5, 1882; Am. Jenks, desert 640, June 19, 1883; William Jenks, desert 640, June 19, 1883; J. G. Huling, pre-emption 160, January 2, 1885; A. G. Lourey, pre-emption, November, 1883, 160.
5. How many acres are now under cultivation?—About 4,000 acres in hay land and other crops.
6. By what ditch or ditches is it watered—L. Z. ditch and Voorhees ditch.
7. From what stream or streams is water taken?—L. Z. ditch, Rawhide Creek; Voorhees, Niobrara Creek.
8. Give history of construction of ditch.—Commencement of ditches were in 1880, completed 1883.

(*a*) Names of owners, Luke Voorhees & Company.

(*b*) Date begun and time occupied in building?—1880, about three years in completing.

(*c*) Dimensions.—Voorhees, 4 feet on top, 3.6 on bottom; length, miles, 6½; depth, 2 feet average; width, 5.4 feet top, 3.6 bottom.

(*d*) How many acres does it water?—Four thousand acres.

(*e*) What was the cost of construction?—About——

(*f*) What is the cost per year for management and repairs?—Am not able to state now.

9. Do you buy or sell water; if so, state price paid or received.—Neither buy nor sell.
10. Have you all the water needed; if not, state the reasons.—Have sufficient water except in some very dry seasons.
11. What is the usual cost of bringing wild land under cultivation? This to include plowing, grubbing sage brush, fencing, etc.—From $7 to $25.
12. How many years' cultivation are required to bring wild land into proper condition for farming?—One to three years.
13. What did it cost you to prove up and obtain title to your land and what was the length of time required? If any difficulties were encountered state what they were.—From six months to three years in proving up. The usual difficulties of constructing ditches and other labor.
14. What has your cultivated land cost you per acre? This to include cost of proving up, cost of ditches and laterals, expense of preparing land for cultivation, fencing, and all permanent improvements?—About $23 per acre.
15. What is its present market value per acre?—Under the rulings of land commissioner for the five years from 1884 to the present time I can hardly say, as it has a market value, no titles.
16. Can you raise crops without irrigation? If so, state what they are and yields obtained.—Can raise no crop without irrigation.
17. Do you think the present land laws are adapted to the conditions of this Territory? If not, what changes would you suggest?—I can suggest no changes to the land laws that were passed prior to 1881. It is the rulings of land commissioners that are dangerous to settle.
18. What should be done with grazing land which can not be irrigated? What is its value per acre?—On an average not to exceed 10 cents per acre; should be donated to the State or Territory for schools and public buildings.
19. How do you regard the withdrawal of all public land from settlement during the irrigation survey?—I regard it as very dangerous and detrimental to the best interests of the citizens and Territory in general.
20. Do you favor the donation of all irrigable public land to the Territory?—I do. I believe it would be better for the General Government to donate to State or Territory.

Name, **Benj. F. Lowe**; county, Fremont; postoffice, Lander.

1. How long have you resided in the Territory?—Twenty-one years.
2. In what year did you begin farming?—1870.
3. How much land have you under ditch?—Thirty acres.
4. If obtained from the Government, state the filings which were made.—Cash entry for N.E. ¼, Sec. 18, Town. 33, Range 99 west Sixth principal meridian.
5. How many acres are now under cultivation?—About 30.
6. By what ditch or ditches is it watered?—By two ditches taken out of the Big Popoagie.

7. From what stream or streams is water taken?—The Big Popoagie River.

8. Give history of construction of ditch.—Were made by me in the year 1875.

(a) Names of owners.—Self.

(b) Date begun and time occupied in building.—Three or four days.

(c) Dimensions, 150 inches; length, one-half mile; depth, 10 inches; width, 18 inches.

(d) How many acres does it water?—Ten.

(e) What was the cost of construction?—Twenty dollars.

(f) What is the cost per year for management and repairs?—One dollar.

9. Do you buy or sell water; if so, state price paid on received.—Sell no water; buy none.

10. Have you all the water needed; if not, state the reason.—No; the Lander Mill Company has taken the water from its proper channel for their own use.

11. What is the usual cost of bringing wild land under cultivation? This to include plowing, grubbing sage brush, fencing, etc.—About $10 per acre.

12. How many years' cultivation are required to bring wild land into proper condition for farming?—Good as ever first year.

13. What did it cost you to prove up and obtain title to your land and what was the length of time required? If any difficulties were encountered, state what they were.—About $600. The town of Lander is located on N.E. ¼, Sec. 18. There were some persons other than myself living on the land, hence some additional cost. Time in obtaining title, sixteen months.

14. What has your cultivated land cost you per acre? This to include cost of proving up, cost of ditches and laterals, expense of preparing land for cultivation, fencing, and all permanent improvements.—About $2,000; 160 acres.

15. What is its present market value per acre?—From $50 to $500.

16. Can you raise crops without irrigation? If so, state what they are and yields obtained.—Some of the bottom land on the streams of Big Popoagie will produce average crop without irrigation; 95 per cent. of Wyoming requires water, more or less.

17. Do you think the present land laws are adapted to the conditions of this Territory? If not, what changes would you suggest?—The laws are all that could be asked as regards homesteads and desert entries; tree culture is a failure.

18. What should be done with grazing land which can not be irrigated? What is its value per acre?—They might be leased by stockmen; artesian wells put down at great expense would bring the lands up to a rate that would re-imburse the State.

19. How do you regard the withdrawal of all public land from settlement during the irrigation survey?—Do not think it necessary; new settlers will not be in the way.

20. Do you favor the donation of all irrigable public land to the Territory?—Yes.

Name, JOHN O. D. O'BRIEN; county, Converse; post-office, Douglas.

1. How long have you resided in the Territory?—Twenty-two years.

2. In what year did you begin farming?—1877.

3. How much land have you under ditch?—About 80 acres.

4. If obtained from the Government, state the filings which were made.—No filings made on account of Government survey of Fetterman Reservation, includes my claim, and no filing can be made until act of Congress is carried out.

5. How many acres are now under cultivation?—Fifteen acres.

6. By what ditch or ditches is it watered?—O'Brien's Ditch.

7. From what stream or streams is water taken?—La Prele Creek.

8. Give history of construction of ditch:

(a) Names of owners. O'Brien & Wallace, Burt Elder, and W. H. Powell.

(b) Date begun and time occupied in building.—November 11, 1887. One month.

(c) Dimensions, 4 feet; length, 3 miles; depth, 1 foot; width, 4 feet.

(d) How many acres does it water?—Two hundred and forty.

(e) What was the cost of construction?—About $1,000.

(f) What is the cost per year for management and repairs?—Forty to fifty dollars.

9. Do you buy or sell water; if so, state price paid or received?—No.

10. Have you all the water needed; if not state the reason?—Yes.

11. What is the usual cost of bringing wild land under cultivation? This to include plowing, grubbing sage brush, fencing, etc.—Ten dollars per acre.

12. How many years cultivation are required to bring wild land into proper condition for farming?—Three years.

13. What did it cost you to prove up and obtain title to your land and what was the length of time required? If any difficulties were encountered, state what they were?—Congress passed an act to sell the reservation of Fetterman, except what land was occupied by settlers, January 1, 1884, but it seems we are no nearer to-day to file than we were five years ago.

14. What has your cultivated land cost you per acre? This to include cost of ditches and laterals, expense of preparing land for cultivation, fencing, and all permanent improvements.—Ten dollars per acre.

15. What is its present market value per acre?—Nothing until patent is obtained, to which I should have been entitled at least eleven years ago.

16. Can you raise crops without irrigation? If so, state what they are and yields obtained?—No.

17. Do you think the present land laws are adapted to the conditions of this Territory? If not, what changes would you suggest?—No; an extra grant of, say, 160 acres of hilly land for pasture of grangers' cattle adjoining creek bottoms.

18. What should be done with grazing land which can not be irrigated? What is its value per acre?—Answered in question 17. Could not say; but very little.

19. How do you regard the withdrawal of all public land from settlement during the irrigation survey?—I hardly understand the question, but am not in favor of any public land being withdrawn, for it hinders settlement.

20. Do you favor the donation of all irrigable public land to the Territory?—No; the United States land laws are good enough for me.

Name, T. M. **Herrick**; county, Laramie; post-office, Goshen.

1. How long have you resided in the Territory?—Fourteen years.

2. In what year did you begin farming?—1885.

3. How much land have you under ditch?—Four hundred and fifty acres.

4. If obtained from the Government, state the filings which were made.—Desert.

5. How many acres are now under cultivation?—Two hundred in hay; forty plowed.

6. By what ditch or ditches is it watered?—Spy and Herrick and Bolcom.

7. From what stream or streams is water taken?—Big Horse Creek.

8. Give history of construction of ditch:

(*a*) Names of owners.—T. M. Herrick and wife.

(*b*) Date begun and time occupied in building.—Spy ditch, March, 1885; five months.

(*c*) Dimensions, Spy ditch, length, 1¼ miles; depth, 1 foot; width, 5 feet.

(*d*) How many acres does it water?—Three hundred.

(*e*) What was the cost of construction?—Eight hundred dollars.

(*f*) What is the cost per year for management and repairs?—Twenty-five dollars.

9. Do you buy or sell water? If so, state price paid or received.—In the Spy Ditch, no.

10. Have you all the water needed. If not, state the reason.—Because the water is taken out above me.

11. What is the usual cost of bringing wild land under cultivation; this to include plowing, grubbing sage brush, fencing, etc.?—Some $1; some $5.

12. How many years' cultivation are required to bring wild land into proper condition for farming?—Two.

13. What did it cost you to prove up and obtain title to your land, and what was the length of time required? If any difficulties were encountered, state what they were.—Four dollars per acre; two years.

14. What has your cultivated land cost you per acre; this to include cost of proving up; cost of ditches and laterals, expense of preparing land for cultivation, fencing, and all permanent improvements?—Six dollars.

15. What is its present market value per acre?—Nothing.

16. Can you raise crops without irrigation? If so, state what they are and yields obtained.—No.

17. Do you think the present land laws are adapted to the conditions of this Territory? If not, what changes would you suggest?—All but pre-emption and timber claims; they ought to be repealed.

18. What should be done with grazing land which can not be irrigated? What is its value per acre?—Sold in 1,000-acre lots; 50 cents per acre.

19. How do you regard the withdrawal of all public land from settlement during the irrigation survey?—It would ruin the Territory for the time continued.

20. Do you favor the donation of all irrigable public land to the Territory?—Yes.

Name, **Caleb M. La Grange**; county, Laramie; post-office, Goshen.

1. How long have you resided in the Territory?—Twenty-two years.

2. In what year did you begin farming?—1871.

3. How much land have you under ditch?—Eight hundred acres.

4. If obtained from the Government, state the filings which were made.—Under the desert land laws.

5. How many acres are now under cultivation?—Six hundred.

6. By what ditch or ditches is it watered?—Brown & La Grange Ditch.

7. From what stream or streams is water taken.—Horse Creek.

8. Give history of construction of ditch:

(*a*) Name of owners.—D. E. Brown, C. M. La Grange.

(*b*) Date begun and time occupied in building.—March 23, 1883; one year.

(*c*) Dimensions; length 4 miles; North Fork 2 miles; depth, 2 feet; width 13 feet on top and 6 feet on bottom.

(*d*) How many acres does it water?—Twenty-three hundred.

(*e*) What was the cost of construction?—Main ditch, $1,600; my own laterals $300.

(*f*) What is the cost per year for management and repairs?—$150.

9. Do you buy or sell water? If so, state price paid or received.—Do not buy or sell.

10. Have you all the water needed? If not, state the reason.—Have not; water taken by other ditches above.

11. What is the usual cost of bringing wild land under cultivation; this to include plowing, grubbing sage brush, fencing, etc.?—Four dollars.

12. How many years' cultivation are required to bring wild land into proper condition for farming?—Two.

13. What did it cost you to prove up and obtain title to your land and what was the length of time required? If any difficulties were encountered, state what they were.—Made proof in two years and six months after filing; cost $1,200.

14. What has your cultivated land cost you per acre; this to include cost of proving up, cost of ditches and laterals, expense of preparing land for cultivation, fencing and all permanent improvements?—6\frac{75}{100}$.

15. What is its present market value per acre?—From $5 to to $15.

16. Can you raise crops without irrigation? If so, state what they are and yields obtained.—No.

17. Do you think the present laws are adapted to the conditions of this Territory? If not, what changes would you suggest?—Free gift of 320 acres to every man or woman that will live on it for five years.

18. What should be done with grazing land which can not be irrigated? What is its value per acre?—Fifty cents. It should be sold to highest bidder, section at a time.

19. How do you regard the withdrawal of all public land from settlement during the irrigation survey?—It would act on the Territory like a wet blanket on a buffalo-chip fire.

20. Do you favor the donation of all irrigable public land to the Territory?—On condition, no.

Name, **Lionel Saratoris**; county, Albany; post-office, Laramie; manager of the Douglass, Willar and Saratoris Company.

1. How long have you resided in the Territory?—Seven years.

2. In what year did you begin farming?—1887.

3. How much land have you under ditch?—Twelve thousand acres irrigated, 25,000 acres under ditches not irrigated through scarcity of water.

4. If obtained from the Government, state the filings which were made?—About 8,000 obtained from Government, balance railroad land.

5. How many acres are now under cultivation?—Five hundred and fifty acres in oats and other grains, 800 acres in timothy hay, 3,000 native hay, balance of irrigated land as pasture.

6. By what ditch or ditches is it watered?—Snake Ditch and Taback Ditch and Sernatatle Snake Ditch.

7. From what stream or streams is water taken?—Little Laramie, Big Laramie, Mill and Dutton Creeks.

8. Give history of construction of ditch:

(*a*) Names of owners—Douglas, Willar, and Saratoris Company.

(*b*) Date begun and time occupied in building?—Snake Ditch, 1886; Taback Ditch, 1888.

(*c*) Dimensions: 6 miles, 14 miles; depth, 3 feet, 3½ feet; width, 8 feet, 12 feet.

(*d*) How many acres does it water?—See question 3.

(*e*) What was the cost of construction?—Taback $1,200 per mile, Snake $675.

(*f*) What is the cost per year for management and repairs?—About 3 per cent. original cost first year, afterwards 1 per cent.

9. Do you buy or sell water? If so, state price paid or received.—[No answer.]

10. Have you all the water needed? If not, state the reason.—Not for the last two years, on account of mild winters, when there is no snow on the mountains.

11. What is the usual cost of bringing wild land under cultivation? This to include plowing, grubbing sage brush, fencing, etc.—One hundred and twenty-five dol-

lars per mile. I have never grubbed sage-brush, as I have so much good land without any that it does not pay to grub the land.

12. How many years' cultivation are required to bring wild land into proper condition for farming?—Two years.

13. What did it cost you to prove up and obtain title to your land, and what was the length of time required? If any difficulties were encountered, state what they were.—Three dollars and fifty cents per acre to $4.50. Two years in most cases. No difficulties except gross ignorance on the part of the Cheyenne land office.

14. What has your cultivated land cost you per acre? This to include cost of proving up, cost of ditches and laterals, expense of preparing land for cultivation, fencing, and all permanent improvements.—A very hard question. I answer, about $9 to $15 per acre.

15. What is its present market value per acre?—I consider good meadow $15 per acre, cultivated land $35 per acre, with crop on land.

16. Can you raise crops without irrigation? If so, state what they are and yields obtained.—I am confident that crops can be raised without irrigation if land is plowed and allowed to fallow for one year, then to sow some quick-growing crop. Have it all so as to collect snow, and thus permanently loosen up the subsoil.

17. Do you think the present land laws are adapted to the conditions of this Territory? If not, what changes would you suggest?—All laws are satisfactory, but I think that people who control a large amount of land should be allowed to take up in some several sections of high land for purposes of pasture. I mean lands that are impossible to irrigate and that the "honest settler" has no use for. This will be better than the present unsatisfactory conditions of Government uplands. This quality of land is of no value except to large land-owners who have many cattle, and they should be allowed to control it either by lease or sale. These lands have always been the great impediment to Eastern capital coming into this Territory.

19. How do you regard the withdrawal of all public land from settlement during the irrigation survey?—I see no use for doing this.

20. Do you favor the donation of all irrigable public land to the Territory?—Yes; as long as the Territory is not allowed to put exorbitant prices on the uplands they should still in some way be controlled by Government, and county commissioners should have nothing to say in the matter of selling or trading these lands.

Name, **John R. Smith**; county, Johnson; post-office, Traburg.

1. How long have you been in the Territory?—Twenty-three years.

2. In what year did you begin farming?—1879.

3. How much land have you under ditch?—One thousand two hundred acres.

4. If obtained from the Government, state the filings which were made.—One homestead, one timber culture, two desert claims.

5. How many acres are now under cultivation?—About 800—400 pasture.

6. By what ditch or ditches is it watered?—The John R. Smith Ditch.

7. From what stream or streams is water taken?—Crazy Woman's Fork of Powder.

8. Give history of construction of ditch:

(*a*) Names of owners, John R. Smith, Agnes Smith.

(*b*) Date begun and time occupied in building?—10th day of April, 1879.

(*c*) Dimensions: Length, 6 miles; depth, 2 feet; width, 7 feet.

(*d*) How many acres does it water?—Ten thousand.

(*e*) What was the cost of construction?—Six hundred dollars.

(*f*) What is the cost per year for management and repairs?—On average, $75.

9. Do you buy or sell water? If so, state price paid or received.—[No answer.]

10. Have you all the water needed? If not, state the reason.—I have not this year; and 1886 and 1887 was short, caused by other ditches using it.

11. What is the usual cost of bringing wild land under cultivation? This to include plowing, grubbing sage-brush, fencing, etc.—Mine has cost me about $850, not including Government cost.

12. How many years' cultivation are required to bring wild land into proper condition for farming?—Two years.

13. What did it cost you to prove up and obtain title to your land, and what was the length of time required? If any difficulties were encountered, state what they were.—One thousand dollars on 640 acres; $350 on 240 acres; and $20 on 160; timber culture, not proved upon, 160 acres; three years and five years.

14. What has your cultivated land cost you per acre? This to include cost of proving up, cost of ditches and laterals, expense of preparing land for cultivation, fencing, and all permanent improvements.—Thirteen thousand and eighty-five dollars, in full.

15. What is its present market value per acre?—There is no land selling at any price.

16. Can you raise crops without irrigation? If so, state what they are and yields obtained.—You can not raise anything here without water to irrigate with.

17. Do you think the present land laws are adapted to the conditions of this Territory? If not, what changes would you suggest.—I do not think the Territory should own and control her own lands.

18. What should be done with grazing land which can not be irrigated? What is its value per acre?—Five to 20 cents per acre, sold to any one wishing to purchase.

19. How do you regard the withdrawal of all public land from settlement during the irrigation survey?—It will be an injustice to the public.

20. Do you favor the donation of all irrigable public land to the Territory?—I do; strongly.

Name, Gustave E. A. Moeler; county, Johnson; post-office, Buffalo.

1. How long have you resided in the Territory?—Twelve years.

2. In what year did you begin farming?—1879.

3. How much land have you under ditch?—One thousand two hundred and eighty acres.

4. If obtained from the Government, state the filings which were made?—Homestead, pre-emption, and two desert filings.

5. How many acres are now under cultivation?—About 800.

6. By what ditch or ditches is it watered?—North Fork and French Creek Ditch Company's ditch.

7. From what stream or streams is water taken?—North Fork of Clear Creek.

8. Give history of construction of ditch:

(a) Names of owners, North Fork and French Creek Ditch Company (a corporation).

(b) Date begun and time occupied in building?—January 3, 1886; five months.

(c) Dimensions, 112 square feet per section; length, 2 miles; depth, 3 feet; width, 7 feet.

(d) How many acres does it water?—Three thousand.

(e) What was the cost of construction?—Two thousand dollars.

(f) What is the cost per year for management and repairs?—Two hundred dollars.

9. Do you buy or sell water? If so, state price paid or received.—[No answer.]

10. Have you all the water needed? If not, state the reason—I have.

11. What is the usual cost of bringing wild land under cultivation? This to include plowing, grubbing sage-brush, fencing, etc.—The cost to me has been about $12 per acre.

12. How many years' cultivation are required to bring wild land into proper condition for farming?—Three years.

13. What did it cost you to prove up and obtain title to your land and what was the length of time required? If any difficulties were encountered, state what they were.—I paid the United States $1.25 per acre for 1,120 acres. It took nine years to get title to my homestead; six years for my desert. For 800 acres I have no title yet, although final proof has been made.

14. What has your cultivated land cost you per acre? This to include cost of proving up, cost of ditches and laterals, expense of preparing land for cultivation, fencing, and all permanent improvements.—Answered above.

15. What is its present market value per acre?—Ten to twelve dollars.

16. Can you raise crops without irrigation? If so, state what they are and yields obtained?—Not a spear of grass long enough to cut with a mower.

17. Do you think the present land laws are adapted to the conditions of this Territory? If not, what changes would you suggest?—I have none to suggest. Desert law ought not to be repealed.

18. What should be done with grazing land which can not be irrigated? What is its value per acre?—Might be sold without restriction as to quantity salable to one man. About 50 cents to $1.

19. How do you regard the withdrawal of all public land from settlement during the irrigation survey?—Might be a good plan to head off speculators.

20. Do you favor the donation of all irrigable public land to the Territory?—Yes.

Name, John Darbin; county, Carbon; post-office, Darbin.

1. How long have you resided in the Territory?—Twenty-one years.

2. In what year did you begin farming?—1875.

3. How much land have you under ditch?—The company in which I am interested has 400 acres.

4. If obtained from the Government, state the filings which were made?—Desert claim.

5. How many acres are now under cultivation?—One hundred.

6. By what ditch or ditches is it watered?—Darbin Nos. 1, 2, and 3.

7. From what stream or streams is water taken?—Muddy Creek.

8. Give history of construction of ditch:

(a) Name of owners, Darbin Cattle Company or Union Darbin Company.

(b) Date begun and time occupied in building?—[No answer.]

(c) Dimensions: Length, east, 2½ to 3 miles; depth, No. 1, 2 feet; No. 2, 2 feet; No. 3, 2 feet; width, No. 1, 5 feet; No. 2, 4 feet; No. 3, 4 feet.

(d) How many acres does it water?—Four hundred acres.

(e) What was the cost of construction?—Two thousand dollars.

(f) What is the cost per year for management and repairs?—Fifty dollars.

9. Do you buy or sell water. If so, state price paid or received.—Neither buy nor sell.

10. Have you all the water needed? If not, state the reason.—Have not. Failure of stream in summer is the cause.

11. What is the usual cost of bringing wild land under cultivation? This to include plowing, grubbing sage-brush, fencing, etc.—Eight to twelve dollars. Planting and grubbing sage-brush is alone worth $8 per acre.

12. How many years' cultivation are required to bring wild land into proper condition for farming?—Three to five years.

13. What did it cost you to prove up and obtain title to your land and what was the length of time required? If any difficulties were encountered, state what they were.—It was hard work to get the ditches completed within three years. The expense of getting witnesses to Cheyenne was also heavy.

14. What has your cultivated land cost you per acre? This to include cost of proving up, cost of ditches and laterals, expense of preparing land for cultivation, fencing, and all permanent improvements.—Fifteen dollars.

15. What is its present market value per acre?—[No answer.]

16. Can you raise crops without irrigation? If so, state what they are and yields obtained.—Can not raise anything.

17. Do you think the present land laws are adapted to the conditions of this Territory? If not, what change would you suggest?—More time should be given on the desert land proofs.

18. What should be done with grazing land which can not be irrigated? What is its value per acre?—I hardly know as to the first. Its value does not exceed 5 cents per acre.

19. How do you regard the withdrawal of all public land from settlement during the Irrigation Survey?—It would be detrimental.

20. Do you favor the donation of all irrigable public land to the Territory?—[No answer.]

Name, JOHN H. GORDON; county, Laramie; post-office, Little Horse Creek.

1. How long have you resided in the Territory?—Twelve years.

2. In what year did you begin farming?—1871, in Colorado.

3. How much land have you under ditch?—About 1,400 acres.

4. If obtained from the Government, state the filings which were made?—Most of the land I obtained by purchase which was taken up under the pre-emption, homestead, and desert act.

5. How many acres are now under cultivation?—About 1,000 acres.

6. By what ditch or ditches is it watered?—These lands are watered by nine ditches.

7. From what stream or streams is water taken?—Little Horse Creek Mills, Herrick Creeks, Mills Creek Ditch No. 1, and No. 2, and No. 3.

8. Give history of construction of ditch:

(a) Names of owners, Springdale Ditch Company, Herrick ditches No. 1 and No. 2.

(b) Date begun and time occupied in building?—The oldest, 1873; the balance since that time.

(c) Dimensions, from 2 to 8 feet wide; length, 1 to 5 miles; depth, about 18 inches; width, 2 to 8 feet wide.

(d) How many acres does it water?—About 1,000 acres.

(e) What was the cost of construction?—In the neighborhood of $7,000.

(f) What is the cost per year for management and repairs?—About $400.

9. Do you buy or sell water; if so, state price paid or received?—I neither buy nor sell water for the above lands.

10. Have you all the water needed? If not, state the reason.—No; the waters in this section not adjudicated yet.

11. What is the usual cost of bringing wild land under cultivation? This to include plowing, grubbing sage-brush, fencing, etc.—From $15 to $20 per acre.

12. How many years' cultivation are required to bring wild land into proper condition for farming?—Three years.

13. What did it cost you to prove up and obtain title to your land, and what was the length of time required? If any difficulties were encountered, state what they were.—As I said before, I purchased most of the above lands.

14. What has your cultivated land cost you per acre? This to include cost of proving up, cost of ditches and laterals, expense of preparing land for cultivation, fencing, and all permanent improvements.—About $20 per acre.

15. What is its present market value per acre?—About $15 per acre.

16. Can you raise crops without irrigation? If so, state what they are and yields obtained.—No.

17. Do you think the present land laws are adapted to the conditions of this Territory? If not, what changes would you suggest?—No; I should think the Territory ought to be allowed to make laws to govern the settlement of her lands.

18. What should be done with grazing land which cannot be irrigated? What is its value per acre?—It should be left as a common; but there is very little land which can not be irrigated.

19. How do you regard the withdrawal of all irrigable public land from settlement during the Irrigation Survey?—I think it would be a calamity to the Territory.

20. Do you favor the donation of all irrigable public land to the Territory?—Yes.

Name, D. E. Brown; county, Laramie; post-office, Goshen.

1. How long have you resided in the Territory?—Fifteen years.

2. In what year did you begin farming?—1885.

3. How much land have you under ditch?—About 1,400 acres.

4. If obtained from the Government, state the filings which were made?—Two desert, homestead, and tree claim.

5. How many acres are now under cultivation?—One hundred under plow.

6. By what ditch or ditches is it watered?—By Brown and La Grange ditches.

7. From what stream or streams is water taken?—Big Horse Creek.

8. Give history of construction of ditch:

(*a*) Name of owners—D. E. Brown and C. M. La Grange.

(*b*) Date begun and time occupied in building?—March, 1883; two years.

(*c*) Dimensions, 13 by 6 by 2; length, about 6 miles; depth, 2 feet; width, top 13 feet, bottom 6 feet.

(*d*) How many acres does it water?—About 1,800.

(*e*) What was the cost of construction?—My interest $2,000, on main line.

(*f*) What is the cost per year for management and repairs?—One hundred dollars will cover all repairs.

9. Do you buy or sell water? If so, state price paid or received.—No.

10. Have you all the water needed? If not, state the reason.—At all times, not. Because the water is used above us in the newer ditches that have been infringing on our priority of right.

11. What is the usual cost of bringing wild land under cultivation? This to include plowing, grubbing sage brush, fencing, etc.—From $4 to $6 per acre.

12. How many years cultivation are required to bring wild land into proper condition for farming?—For small grains, etc., just as soon as ditches are completed, with water ready for use.

13. What did it cost you to prove up and obtain title to your land and what was the length of time required? If any difficulties where encountered, state what they were.—The land cost me from the Government, including all expense in making final proof, about $1.50 per acre.

14. What has your cultivated land cost you per acre? This to include cost of proving up, cost of ditches and laterals, expense of preparing land for cultivation, fencing and all permanent improvements.—Nine dollars per acre.

15. What is the present market value per acre?—I value it at $15 per acre.

16. Can you raise crops without irrigation? If so, state what they are and yields obtained.—We can not raise crops without irrigation.

17. Do you think the present land laws are adapted to the conditions of this Territory? If not, what changes would you suggest?—I would suggest four years for making final proof on desert entries and that homesteaders be allowed 320 acres where they prove five years' continuous residence.

18. What should be done with grazing land which can not be irrigated? What is its value per acre?—Fifty cents per acre. I would favor its being leased subject to settlement.

19. How do you regard the withdrawal of all irrigable public land from settlement during the Irrigation Survey?—I do not approve of the withdrawal of all public lands during survey, only in sections where they are commencing to operate.

20. Do you favor the donation of all irrigable public land to the Territory?—On certain conditions, I do.

Name, A. M. McLaughtin; county, Laramie; post-office, Davis Ranch.

1. How long have you resided in the Territory?—Twelve years.

2. In what year did you begin farming?—1878.

3. How much land have you under ditch?—One hundred acres.

4. If obtained from the Government, state the filings which were made?—Homestead entry.

5. How many acres are now under cultivation?—One hundred.

6. By what ditch or ditches is it watered?—McLaughtin, Nos. 1, 2, and 6.

7. From what stream or streams is water taken?—North Horse Creek.

8. Give history of construction of ditch:

(*a*) Names of owners. A. and J. McLaughtin.

(*b*) Date begun and time occupied in building?—1874.

(*c*) Dimensions. Length, 2½ miles; depth, 15 inches; width, 2½ to 3 feet.

(*d*) How many acres does it water?—One hundred and sixty.

(*e*) What was the cost of construction?—One thousand dollars.

(*f*) What is the cost per year for management and repairs?—One hundred dollars.

9. Do you buy or sell water; if so, state price paid or received?—No.

10. Have you all the water needed; if not, state the reason?—Used to have water enough, but now failing on account of dry weather.

11. What is the usual cost of bringing wild land under cultivation? This to include plowing, grubbing sage brush, fencing, etc.—Eight to ten dollars per acre.

12. How many years cultivation are required to bring wild land into proper condition for farming?—Three years.

13. What did it cost you to prove up and obtain title to your land and what was the length of time required? If any difficulties were encountered, state what they were.—Five years time and cost of $1.25 per acre.

14. What has your cultivated land cost you per acre? This to include cost of proving up, cost of ditches and laterals, expense of preparing land for cultivation, fencing and all permanent improvements.—Twenty-two dollars per acre.

15. What is its present market value per acre?—Fifteen dollars per acre.

16. Can you raise crops without irrigation? If so, state what they are and yields obtained.—No.

17. Do you think the present land laws are adapted to the conditions of this Territory? If not, what changes would you suggest?—Government should give each man one section of land in fee simple, when he has reclaimed the same.

18. What should be done with grazing land which can not be irrigated? What is its value per acre?—Sell it in limited tracts at from 8 to 12 cents per acre.

19. How do you regard the withdrawal of all irrigable public land from settlement during the irrigation survey?—It would stop all settlement of the Territory.

20. Do you favor the donation of all irrigable public land to the Territory?—[No answer.]

Name, Emma M. Lathan; county, Laramie; post-office, Davis Ranch.

1. How long have you resided in the Territory?—Eighteen years.

2. In what year did you begin farming?—1873.

3. How much land have you under ditch?—Eighty acres.

4. If obtained from the Government, state the filings which were made.—Preemption.

5. How many acres are now under cultivation?—Eighty.

6. By what ditch or ditches is it watered?—Ditch not named.

7. From what stream or streams is water taken?—Spring Creek, a branch of Horse Creek.

8. Give history of construction of ditch:

(*a*) Names of owners.—Emma M. Lathan.

(*b*) Date begun and time occupied in building?—1879; about three years.

(*c*) Dimensions.—Length, 1 mile; depth, 8 inches; width, 3 feet.

(*d*) How many acres does it water?—Eighty.

(*e*) What was the cost of construction?—Two hundred and fifty dollars.

(*f*) What is the cost per year for management and repairs?—Fifty dollars.

9. Do you buy or sell water; if so, state price paid or received?—No.

10. Have you all the water needed; if not, state the reason?—No. Water was not in the creek.

11. What is the usual cost of bringing wild land under cultivation? This to include plowing, grubbing sage brush, fencing, etc.—From $7 to $10.

12. How many years cultivation are required to bring wild land into proper condition for farming?—Two to four years.

13. What did it cost you to prove up and obtain title to your land and what was the length of time required? If any difficulties were encountered, state what they

were.—Two dollars and twenty-five cents, and took about three years. A mistake of date was made by the land office and I had to offer proof a second time.

14. What has your cultivated land cost you per acre? This to include cost of proving up, cost of ditches and laterals, expense of preparing land for cultivation, fencing, and all permanent improvements.—Sixteen to twenty dollars.

15. What is its present market value per acre?—About $15.

16. Can you raise crops without irrigation? If so, state what they are and yields obtained.—No.

17. Do you think the present land laws are adapted to the conditions of this Territory? If not, what changes would you suggest?—I do not know, but I think every settler should have one section of land for reclaiming it.

18. What should be done with grazing land which can not be irrigated? What is its value per acre?—Should be sold at auction or at fixed value; 10 to 25 cents per acre.

19. How do you regard the withdrawal of all public land from settlement during the irrigation survey?—Unfavorably, for it would stop the settlement of the Territory.

20. Do you favor the donation of all irrigable public lands to the Territory?—I do.

Name, T. W. Rutledge; county, Laramie; post-office, Little Horse Creek.

1. How long have you resided in the Territory?—Twenty-two years.

2. In what year did you begin farming?—1883.

3. How much land have you under ditch?—Four thousand eight hundred acres.

4. If obtained from the Government, state the filings which were made?—Homestead, timber-culture, and mostly desert entries.

5. How many acres are now under cultivation?—One hundred and fifty plowed; 2,000 to hay.

6. By what ditch or ditches is it watered?—Rutledge and Hellman Ditch.

7. From what stream or streams is water taken?—Horse Creek.

8. Give history of construction of ditch:

(*a*) Names of owners.—Rutledge and Hellman.

(*b*) Date begun, and time occupied in building.—1883; and was three years in building.

(*c*) Dimensions.—Length, 50 miles; depth, 4 feet to 1 foot; width, 17 feet to 3 feet.

(*d*) How many acres does it water?—Three hundred acres really watered this year, 1889.

(*e*) What was the cost of construction?—Thirty thousand dollars.

(*f*) What is the cost per year for management and repairs?—One thousand dollars.

9. Do you buy or sell water; if so, state price paid or received?—No.

10. Have you all the water needed; if not, state the reason?—No, the last three seasons have been uncommonly dry, and we have no way of holding the water in time of a freshet.

11. What is the usual cost of bringing wild land under cultivation? This to include plowing, grubbing sage brush, fencing, etc.—Seven dollars and fifty cents per acre. No grubbing is necessary.

12. How many years cultivation are required to bring wild land into proper condition for farming?—Three to five years.

13. What did it cost you to prove up and obtain title to your land, and what was the length of time required? If any difficulties were encountered, state what they were.—One dollar and twenty-five cents for land, and $2.00 for each of the six entrymen on the land.

14. What has your cultivated land cost you per acre? This to include cost of proving up, cost of ditches and laterals, expense of preparing land for cultivation, fencing, and all permanent improvements.—Fifteen dollars per acre.

15. What is its present market value per acre?—Twenty-two dollars per acre, but can not sell for $12.

16. Can you raise crops without irrigation? If so, state what they are, and yields obtained.—No.

17. Do you think the present land laws are adapted to the conditions of this Territory? If not, what changes would you suggest?—No; any man that reclaims a section of land should have a free title, and be exempt from taxes for five years.

18. What should be done with grazing land which can not be irrigated? What is its value per acre?—Hold it as a public range; value, 25 cents per acre.

19. How do you regard the withdrawal of all public land from settlement during the irrigation survey?—As extremely detrimental to the Territory.

20. Do you favor the donation of all irrigable public land to the Territory?—I do.

Name, Jno. McLaughlin; county, Laramie; post-office, Davis Ranch.

1. How long have you resided in the Territory?—Twelve years.

2. In what year did you begin farming?—1878.

3. How much land have you under ditch?—Two hundred and forty acres.

4. If obtained from the Government, state the filings which were made?—Desert entry.

5. How many acres are now under cultivation?—Two hundred and forty acres.

6. By what ditch or ditches is it watered?—McLaughlin ditch, No. 5.

7. From what stream or streams is water taken?—North Horse Creek.

8. Give history of construction of ditch:

(a) Names of owners.—A. and J. McLaughlin.

(b) Date begun and time occupied in building?—1874; by Mr. Sanders, about eleven years.

(c) Dimensions. Length, 3¼ miles; depth, 1½ feet; width, 5 feet.

(d) How many acres does it water?—Six hundred.

(e) What was the cost of construction?—One thousand seven hundred dollars.

(f) What is the cost per year for management and repairs?—One hundred dollars.

9. Do you buy or sell water; if so, state price paid or received?—No.

10. Have you all the water needed; if not, state the reason?—Not for the last two seasons, as they have been exceedingly dry.

11. What is the usual cost of bringing wild land under cultivation? This to include plowing, grubbing sage brush, fencing, etc.—Eight dollars to ten dollars per acre.

12. How many years cultivation are required to bring wild land into proper condition for farming?—Three years.

13. What did it cost you to prove up and obtain title to your land, and what was the length of time required? If any difficulties were encountered, state what they were.—Three years time, at a cost of about $2.50 per acre.

14. What has your cultivated land cost you per acre? This to include cost of proving up, cost of ditches and laterals, expense of preparing land for cultivation, fencing and all permanent improvements. Fourteen dollars to fifteen dollars per acre.

15. What is its present market value per acre?—Ten dollars.

16. Can you raise crops without irrigation? If so, state what they are and yields obtained.—No.

17. Do you think the present land laws are adapted to the conditions of this Territory? If not, what changes would you suggest?—Any man that reclaims a section of land should have it in fee simple.

18. What should be done with grazing land which can not be irrigated? What is its value per acre?—Should be sold at 10 cents per acre, and no man or company to have over one section.

19. How do you regard the withdrawal of all irrigable public land from settlement during the irrigation survey?—I think it would stop the settlement of the country.

20. Do you favor the donation of all irrigable public land to the Territory?—[No answer.]

Name, Lizzie D. Johnston; county, Laramie; post-office, Little Horse Creek.

1. How long have you resided in the Territory?—Eight years.

2. In what year did you begin farming?—1881.

3. How much land have you under ditch?—Two hundred and forty acres.

4. If obtained from the Government, state the filings which were made?—Desert entry.

5. How many acres are now under cultivation?—About 200 acres.

6. By what ditch or ditches is it watered?—Johnston Ditch, No. 1.

7. From what stream or streams is water taken?—Little Horse Creek.

8. Give history of construction of ditch:

(a) Names of owners.—J. R. Johnston, Lizzie D. Johnston, Geo. D. Johnston.

(b) Date begun and time occupied in building?—Commenced 1882; about one year.

(c) Dimensions.—Length, 3¼ miles; depth, 18 inches; width, 3½ feet.

(d) How many acres does it water?—About 1,000 acres.

(e) What was the cost of construction?—About $3,000.

(f) What is the cost per year for managment and repairs?—Two hundred and dollars.

9. Do you buy or sell water. If so, state price paid or received.—No.

10. Have you all the water needed? If not, state the reason.—All that is needed.

11. What is the usual cost of bringing wild land under cultivation?—This to include plowing, grubbing sage brush, fencing, etc.—From $8 to $10.

12. How many years cultivation are required to bring wild land into proper condition for farming?—From one to four years.

13. What did it cost you to prove up and obtain title to your land and what was the length of time required? If any difficulties were encountered, state what they were.—Not less than $2 per acre. No difficulties, as I had fully complied with the law.

14. What has your cultivated land cost you per acre? This to include cost of proving up, cost of ditches and laterals, expense of preparing land for cultivation, fencing and all permanent improvements.—Ten dollars.

15. What is its present market value per acre?—Not over $3 per acre.

16. Can you raise crops without irrigation? If so, state what they are and yields obtained.—No.

17. Do you think the present land laws are adapted to the conditions of this Territory? If not, what changes would you suggest?—[No answer.]

18. What should be done with grazing land which can not be irrigated? What is its value per acre?—I do not know.

19. How do you regard the withdrawal of all irrigable public land from settlement during the irrigation survey?—Very unfavorably.

20. Do you favor the donation of all irrigable public land to the Territory?—No.

Name, **Donald Clark**; county, Laramie; post-office, Davis Ranch.

1. How long have you resided in the Territory?—Fifteen years.

2. In what year did you begin farming?—1874.

3. How much land have you under ditch?—One hundred acres.

4. If obtained from the Government, state the filings which were made?—Homestead.

5. How many acres are now under cultivation?—One hundred acres.

6. By what ditch or ditches is it watered?—Horse Creek Ditch, No. 8.

7. From what stream or streams is water taken?—Main fork of Horse Creek.

8. Give history of construction of ditch:

(a) Names of owners.—Donald Clark and Cheyenne Land and Live-stock Company.

(b) Date begun and time occupied in building?—1875; about two years.

(c) Dimensions.—Length, 2½ miles; depth, 1 foot; width, 3 feet.

(d) How many acres does it water?—One hundred.

(e) What was the cost of construction?—Five hundred dollars.

(f) What is the cost per year for management and repairs?—Seventy-five dollars.

9. Do you buy or sell water? If so, state price paid or received.—No.

10. Have you all the water needed; if not, state the reason?—Some seasons there is plenty, but the last two have been short on account of drought.

11. What is the usual cost of bringing wild land under cultivation? This to include plowing, grubbing sage brush, fencing, etc.—From $10 to $12 per acre.

12. How many years cultivation are required to bring wild land into proper condition for farming?—Four years.

13. What did it cost you to prove up and obtain title to your land and what was the length of time required? If any difficulties were encountered, state what they were.—Cost about $1 per acre and five years time.

14. What has your cultivated land cost you per acre? This to include cost of proving up, cost of ditches and laterals, expense of preparing land for cultivation, fencing, and all permanent improvements.—Not less than $14.

15. What is its present market value per acre?—From $8 to $10.

16. Can you raise crops without irrigation? If so, state what they are and yields obtained.—No.

17. Do you think the present land laws are adapted to the conditions of this Territory; if not, what changes would you suggest?—I do not know.

18. What should be done with grazing land which can not be irrigated? What is its value per acre?—From 10 to 25 cents per acre and limit the amount that each actual occupant shall be allowed to purchase not to exceed one section.

19. How do you regard the withdrawal of all irrigable public land from settlement during the irrigation survey?—Very unfavorably.

20. Do you favor the donation of all irrigable public land to the Territory?—I do.

Name, **R. P. Mull**; county of Laramie; post-office, Davis Ranch.

1. How long have you resided in the Territory?—Twenty years.

2. In what year did you begin farming?—1878.

3. How much land have you under ditch?—One hundred and twenty-five acres.

4. If obtained from the Government, state the filings which were made.—Homestead.

5. How many acres are now under cultivation?—One hundred and twenty-five.
6. By what ditch or ditches is it watered?—Mull Ditch, No. 1.
7. From what stream or streams is water taken?—Horse Creek.
8. Give history of construction of ditch:
(*a*) Names of owners.—B. P. and Mary Mull.
(*b*) Date begun and time occupied in building?—1879; three years.
(*c*) Dimensions; length?—1¾ miles; depth, 1 foot; width, 4½ feet.
(*d*) How many acres does it water?—One hundred and twenty-five.
(*e*) What was the cost of construction?—One thousand dollars.
(*f*) What is the cost per year for management and repairs?—One hundred dollars.
9. Do you buy or sell water; if so, state price paid or received?—No.
10. Have you all the water needed; if not, state the reason?—No; where my dam is there is so much sand that the water runs underground.
11. What is the usual cost of bringing wild land under cultivation? This to include plowing, grubbing sage brush, fencing, etc.?—Nine dollars per acre.
12. How many years cultivation are required to bring wild land into proper condition for farming?—Four to seven years.
13. What did it cost you to prove up and obtain title to your land, and what was the length of time required? If any difficulties were encountered, state what they were?—Twelve dollars per acre.
14. What has your cultivated land cost you per acre? This to include cost of proving up, cost of ditches and laterals, expense of preparing land for cultivation, fencing, and all permanent improvements.—Thirty-two dollars per acre.
15. What is its present market value per acre?—Twenty dollars per acre.
16. Can you raise crops without irrigation? If so, state what they are and yields obtained?—No.
17. Do you think the present land laws are adapted to the conditions of this Territory; if not, what changes would you suggest?—No; every citizen that reclaims the land should have, in fee simple, a title to one section of land.
18. What should be done with grazing land which can not be irrigated? What is its value per acre?—Should be sold at 8 to 10 cents per acre, and each person to have not over two sections.
19. How do you regard the withdrawal of all irrigable public land from settlement during the irrigation survey?—Unfavorably, as it would stop all settlement of the Territory.
20. Do you favor the donation of all irrigable public land to the Territory?—I do.

Name, AUGUSTUS TRABING; county, Albany; post-office, Laramie.
1. How long have you resided in the Territory?—Twenty-one years.
2. In what year did you begin farming?—1886.
3. How much land have you under ditch?—Sold out; had 800 acres.
4. If obtained from the Government, state the filings which were made?—I bought it from the Wyoming Central Land and Improvement Company.
5. How many acres are now under cultivation?—Twenty acres. Rest in grass.
6. By what ditch or ditches is it watered?—Pioneer Canal.
7. From what stream or streams is water taken?—Big Laramie River.
8. Give history of construction of ditch:
(*a*) Name of owners —Pioneer Canal Company.
(*b*) Date begun and time occupied in building?—Completed in 1886.
(*c*) Dimensions: Length, 35 miles; depth, 4 feet; width, 16 feet.
(*d*) How many acres does it water?—Twenty thousand.
(*e*) What was the cost of construction?—Fifty thousand dollars.
(*f*) What is the cost per year for management and repairs?—Twelve hundred dollars.
9. Do you buy or sell water; if so, state price paid or received?—Buy; 50 cents per acre.
10. Have you all the water needed; if not, state the reason?—Did have.
11. What is the usual cost of bringing wild land under cultivation? This to include plowing, grubbing sage brush, fencing, etc.—Five dollars per acre.
12. How many years cultivation are required to bring wild land into proper condition for farming?—Three.
13. What did it cost you to prove up and obtain title to your land, and what was the length of time required? If any difficulties were encountered, state what they were?—I paid $10 per acre, as it was only 2 miles from Laramie, Wyo.
14. What has your cultivated land cost you per acre? This to include cost of proving up, cost of ditches and laterals, expense of preparing land for cultivation, fencing, and all permanent improvements?—Twenty dollars, but I made extensive improvements.

15. What is its present market value per acre?—Sold for $40 last May, with all stock and improvements, net about $30 per acre.

16. Can you raise crops without irrigation? If so, state what they are and yields obtained?—No.

17. Do you think the present land laws are adapted to the conditions of this Territory? If not, what changes would you suggest?—No. Let each man have a section of desert-land for homestead on reclamation.

18. What should be done with grazing land which can not be irrigated? What is its value per acre?—Give it to Territory, value about 25 cents.

19. How do you regard the withdrawal of all public land from settlement during the irrigation survey?—A withdrawal for one year is all right.

20. Do you favor the donation of all irrigable public land to the Territory?—Yes.

Name, C. W. Holden; county, Uinta; post-office; Fontenelle.

1. How long have you resided in the Territory?—Nearly thirteen years.

2. In what year did you begin farming?—1877.

3. How much land have you under ditch?—About 800 acres.

4. If obtained from the Government, state the filings which were made?—Homestead and pre-emption, desert, and timber-culture, also lease of school land.

5. How many acres are now under cultivation?—About 800 acres.

6. By what ditch or ditches is it watered?—Nos. 1, 2, 3, and 4.

7. From what stream or streams is water taken?—Fontenello.

8. Give history of construction of ditch:

(a) Names of owners—C. W. Holden.

(b) Date begun and time occupied in building?—No. 1 was commenced in 1878.

(c) Dimensions: Length, 4 miles; depth, 1 to 2 feet; width, 4 to 6 feet.

(d) How many acres does it water?—About 800.

(e) What was the cost of construction?—About $1 per rod.

(f) What is the cost per year for management and repairs?—Not far from $200.

9. Do you buy or sell water; if so, state price paid or received?—No.

10. Have you all the water needed; if not, state the reason?—Yes. Have had so far.

11. What is the usual cost of bringing wild land under cultivation? This to include plowing, grubbing sage brush, fencing, etc?—About $10.

12. How many years cultivation are required to bring wild land into proper condition for farming?—About two.

13. What did it cost you to prove up and obtain title to your land and what was the length of time required? If any difficulties were encountered, state what they were.—My homestead cost two usual fees and about $50 for incidental expenses; have not final proof on the other entries.

14. What has your cultivated land cost you per acre? This to include cost of proving up, cost of ditches and laterals, expense of preparing land for cultivation, fencing, and all permanent improvements.—Twelve dollars to fifteen dollars.

15. What is its present market value per acre?—Don't know.

16. Can you raise crops without irrigation? If so, state what they are and yields obtained?—No.

17. Do you think the present land laws are adapted to the conditions of this Territory? If not, what changes would you suggest?—Give the desert land to the man who reclaims and reduces it to cultivation upon final proof that he has done so.

18. What should be done with grazing land which can not be irrigated? What is its value per acre?—Lands not susceptible of irrigation are of little value for any purpose; after the water-courses are all fenced.

19. How do you regard the withdrawal of all public land from settlement during the irrigation survey?—It would virtually stop immigration and could ouly benefit wealthy grazers.

20. Do you favor the donation of all irrigable public land to the Territory?—Yes.

Name, Edwin C. Smith; county, Converse; post-office, Douglas.

1. How long have you resided in the Territory?—Since April 4, 1873; sixteen years.

2. In what year did you begin farming?—1881.

3. How much land have you under ditch?—Three hundred and twenty acres.

4. If obtained from the Government, state the filings which were made.—One hundred and sixty homestead, 160 pre-emption.

5. How many acres are now under cultivation?—Thirty plow, 50 hay, balance pasture.

6. By what ditch or ditches is it watered?—My own ditch.
7. From what stream or streams is water taken?—Laprelle Creek.
8. Give history of construction of ditch:

(*a*) Names of owners—First ditch made by Joseph Hornbeck in 1887; I bought and reconstructed it.

(*b*) Date begun and time occupied in building?—1881; have forgotten exact date when finished.

(*c*) Dimensions: Length, 2 miles; depth, 1 foot; width, 5 feet.

(*d*) How many acres does it water?—About 100 acres.

(*e*) What was the cost of construction?—Five hundred dollars.

(*f*) What is the cost per year for management and repairs?—Can't state exactly.

9. Do you buy or sell water; if so, state price paid or received?—Do not sell.

10. Have you all the water needed; if not, state the reason?—Have when ditch is in good order, sometimes have breaks in ditch.

11. What is the usual cost of bringing wild land under cultivation? This to include plowing, grubbing sage brush, fencing, etc.—About $10.

12. How many years cultivation are required to bring wild land into proper condition for farming?—Three.

13. What did it cost you to prove up and obtain title to your land and what was the length of time required? If any difficulties were encountered state what they were.—Distance from land office when filings were made; received every courtesy from officials of land office.

14. What has your cultivated land cost you per acre? This to include cost of proving up, cost of ditches and laterals, expense of preparing land for cultivation, fencing, and all permanent improvements.—About $12.

15. What is its present market value per acre?—Can't state, as no sales are being made.

16. Can you raise crops without irrigation; if so, state what they are and yields obtained?—No; sometimes potatoes, but very seldom.

17. Do you think the present land laws are adapted to the conditions of this Territory; if not, what changes would you suggest?—Haven't any suggestion to make; am satisfied with the present land laws.

18. What should be done with grazing land which can not be irrigated? What is its value per acre?—Leave them, as they are a benefit to the settlers for grazing purposes.

19. How do you regard the withdrawal of all public land from settlement during the irrigation survey?—Favorable; don't exactly understand it.

20. Do you favor the donation of all irrigable public land to the Territory?—Can't say.

Name, A. L. SUTHERLAND; county, Albany; post-office, Sherman.

1. How long have you resided in the Territory?—Eleven years.
2. In what year did you begin farming?—In 1881.
3. How much land have you under ditch?—One hundred and twenty acres.
4. If obtained from the Government, state the filings which were made.—Homestead and also railroad lands.
5. How many acres now under cultivation?—One hundred and thirty-five.
6. By what ditch or ditches is it watered?—Private.
7. From what stream or streams is water taken?—Dale Creek, Pump Creek, and springs.
8. Give history of construction of ditch.—It was begun in 1872, and lengthened from time to time.

(*a*) Name of owner.—A. L. Sutherland.

(*b*) Date begun and time occupied in building.—1872, time of building not known.

(*c*) Dimensions.—Length, 3 miles; depth, 2 feet; width, 3 feet.

(*d*) How many acres does it water?—Forty.

(*e*) What was the cost of construction?—Six hundred dollars.

(*f*) What is the cost per year for management and repairs? [No answer.]

9. Do you buy or sell water. If so, state price paid or received.—Do not sell.

10. Have you all the water needed? If not, state the reason.—Have not, as those who have taken out ditches about me use all there is at times.

11. What is the usual cost of bringing wild land under cultivation? This to include plowing, grubbing sage brush, fencing, etc.—Ten dollars.

12. How many years cultivation are required to bring wild land into proper condition for farming?—Two.

13. What did it cost you to prove up and obtain title to your land, and what was the length of time required? If any difficulties were encountered, state what they were.—Cost $72.60. Had the best of proof, but patent is delayed over three years. Has not arrived yet.

14. What has your cultivated land cost you per acre? This to include cost of proving up, cost of ditches and laterals, expense of preparing land for cultivation, fencing, and all permanent improvements.—Twelve dollars.

15. What is its present market value per acre?—Twelve dollars.

16. Can you raise crops without irrigation? If so, state what they are and yields obtained?—Can not.

17. Do you think the present laws are adapted to the conditions of this Territory? If not, what changes would you suggest?—That patents should be issued within six months after final proof.

18. What should be done with grazing land which can not be irrigated? What is its value per acre?—One dollar and seventy-five cents. Thrown open to all not fenced in with railroad land.

19. How do you regard the withdrawal of all public land from settlement during the irrigation survey?—I think there should be restrictions on it.

20. Do you favor the donation of all irrigable public land to the territory?—I do.

Name, J. F. ROCHE; county, Laramie; post-office, Wendover.

1. How long have you resided in the Territory?—Three years.

2. In what year did you begin farming?—1886.

3. How much land have you under ditch?—Three hundred acres.

4. If obtained from the Government, state the filings which were made?—Homestead and desert.

5. How many acres are now under cultivation?—Fifty.

6. By what ditch or ditches is it watered?—Jumbo.

7. From what stream or streams is water taken?—Cottonwood Creek.

8. Give history of construction of ditch:

(*a*) Name of owner.—J. F. Roche.

(*b*) Date begun and time occupied in building.—September, 1886. Completed in 1887.

(*c*) Dimensions.—Length, 2½ miles; depth, from 1 to 8 feet; width, 8 feet.

(*d*) How many acres does it water?—Covers about 300 acres, but water is insufficient.

(*e*) What was the cost of construction?—Five hundred dollars.

(*f*) What is the cost per year for management and repairs?—Twenty-five dollars.

9. Do you buy or sell water? If so, state price paid or received.—No.

10. Have you all the water needed? If not, state the reason.—No water in the stream after about July 1.

11. What is the usual cost of bringing wild land under cultivation? This to include plowing, grubbing sage brush, fencing, etc.—Six dollars.

12. How many years cultivation are required to bring wild land into proper condition for farming?—Three years.

13. What did it cost you to prove up and obtain title to your land, and what was the length of time required? If any difficulties were encountered state what they were.—Not proved up.

14. What has your cultivated land cost you per acre? This to include cost of proving up, cost of ditches and laterals, expense of preparing land for cultivation, fencing, and all permanent improvements.—Six dollars.

15. What is the present market value per acre?—No fixed value.

16. Can you raise crops without irrigation? If so, state what they are and yields obtained.—Yes; have raised corn, wheat, oats, alfalfa, potatoes, and vegetables.

17. Do you think the present land laws are adapted to the conditions of this Territory? If not, what changes would you suggest?—No. I should suggest that all lands redeemable by irrigation should be given to parties redeeming the same without the necessary $1.25 per acre.

18. What should be done with grazing land which can not be irrigated? What is its value per acre?—Should be leased to settlers at nominal figures.

19. How do you regard the withdrawal of all public land from settlement during the irrigation survey?—Do not think it proper.

20. Do you favor the donation of all irrigable public land to the Territory?—Yes.

Name, HAINES BROS.; county, Carbon; post-office, Saratoga.

1. How long have you resided in the Territory?—Six years.

2. In what year did you begin farming?—1883.

3. How much land have you under ditch?—Two thousand five hundred acres.

4. If obtained from the Government, state the filings which were made?—Desert and pre-emption filings.

5. How many acres are now under cultivation?—About 250.

6. By what ditch or ditches is it watered?—Haines Ditch and other small ditches.

7. From what stream or streams is water taken?—North and South Spring Creek.

8. Give history of construction of ditch:

(*a*) Names of owners.—J. G. Haines, H. W. Haines, and M. Haines.

(*b*) Date begun and time occupied in building?—May 1, 1885; time, four months.

(*c*) Dimensions.—11 by 8 by 2; length, 11 miles; depth, 2 feet; width, 11 feet. Five miles of this ditch on a grade of 4 feet to the mile is of above dimensions; 3 miles natural water course; balance, owing to heavier grades, smaller.

(*d*) How many acres does it water?—Two thousand.

(*e*) What was the cost of construction?—Four thousand dollars.

(*f*) What is the cost per year for management and repairs?—Fifty dollars.

9. Do you buy or sell water? If so, state price paid or received.—No.

10. Have you all the water needed? If not, state the reason.—During high water have plenty, but last of the season not enough water in creek to fill ditch.

11. What is the usual cost of bringing wild land under cultivation? This to include plowing, grubbing sage brush, fencing, etc.—From $5 to $10 per acre.

12. How many years cultivation are required to bring wild land into proper condition for farming?—Most land a fair crop first year.

13. What did it cost you to prove up and obtain title to your land and what was the length of time required? If any difficulties were encountered, state what they were.—Cost, $1.25 per acre, with addition of advertising and agents' fees.

14. What has your cultivated land cost you per acre? This to include cost of proving up, cost of ditches and laterals, expense of preparing land for cultivation, fencing, and all permanent improvements.—Ten dollars per acre.

15. What is its present market value per acre?—Thirty dollars per acre.

16. Can you raise crops without irrigation? If so, state what they are and yields obtained.—No.

17. Do you think the present land laws are adapted to the conditions of this Territory? If not, what changes would you suggest?—Let them remain as they are.

18. What should be done with grazing land which can not be irrigated? What is its value per acre?—Left open to the public. Varies from nothing up.

19. How do you regard the withdrawal of all public land from settlement during the irrigation survey?—Do not regard it favorably.

20. Do you favor the donation of all irrigable public land to the Territory?—No.

Name, ED B. CHAPLIN; county, Johnson; post-office, Buffalo.

1. How long have you resided in the Territory?—At intervals since 1867. Continuously thirteen years.

2. In what year did you begin farming?—In Wyoming in 1879.

3. How much land have you under ditch?—About 200 acres, originally 320 acres.

4. If obtained from the Government, state the filings which were made.—Desert.

5. How many acres are now under cultivation?—One hundred and eighty nearly; garden 20, hay 160.

6. By what ditch or ditches is it watered?—Snider Ditch No's 1 and 2, Four Lakes and French Creek Ditches and Flume Company's.

7. From what stream or streams is water taken?—Clear fork of Powder River and French Creek.

8. Give history of construction of ditch:

(*a*) Names of owners, Snider Ditch No. 1, E. M. Snider and myself; Four Lakes and French Creek O. J. Wastman, R. S. Hopkins, H. R. Mann, F. Meyers, P. Georgen.

(*b*) Date begun and time occupied in building?—Three months; three and a half months.

(*c*) Dimensions: 5 feet, 10 feet; length, 3 miles, 1½ miles; depth, 2 feet, 2½ feet; width, top, 9 feet, top, 15 feet.

(*d*) How many acres does it water?—Seven hundred acres. Don't know how many acres Four Lakes and French Creek Ditch waters, but think about 5,000 acres.

(*e*) What was the cost of construction?—Snider No. 1, $600; Four Lakes and French Creek, about $1,000.

(*f*) What is the cost per year for management and repairs?—Snider No. 1, about $50; Four Lakes and French Creek, $350.

9. Do you buy or sell water; if so, state price paid or received?—[No answer.]

10. Have you all the water needed; if not, state the reason?—Have this season had all the water needed, but not in former years at times, because it was appropriated by parties above me, who had no right to it.

11. What is the usual cost of bringing wild land under cultivation? This to include plowing, grubbing sage brush, fencing, etc.—Ordinary hay land $12 to $25 per acre, garden $150 approximated.

12. How many years cultivation are required to bring wild land into proper condition for farming?—Three to five.

13. What did it cost you to prove up and obtain title to your land and what was the length of time required? If any difficulties were encountered, state what they were?—Actual cost was $550 to get final receipt. Have not received patent yet, although I proved in May, 1883.

14. What has your cultivated land cost you per acre? This to include proving up, cost of ditches and laterals, expense of preparing land for cultivation, fencing, and all permanent improvements.—Thirty-two dollars and sixty three cents per acre.

15. What is its present market value per acre?—About $50.

16. Can you raise crops without irrigation? If so, state what they are and yields obtained?—Nothing without water.

17. Do you think the present land laws are adapted to the conditions of this Territory? If not, what changes would you suggest?—[No answer.]

18. What should be done with grazing land which can not be irrigated? What is its value per acre?—Should lease to stockmen. It is very difficult to fix value.

19. How do you regard the withdrawal of all public land from settlement during the irrigation survey?—If the survey does not continue too long lands should be withdrawn to guard against speculation in reservoir sites

20. Do you favor the donation of all irrigable public land to the Territory?—I do.

Name, **Chas. A. Pollard**, county of Converse; post-office at Labonte.

1. How long have you resided in the Territory?—Twelve years.

2. In what year did you begin farming?—In 1878.

3. How much land have you under ditch?—Six hundred acres.

4. If obtained from the Government, state the filings which were made.—Pre-emption No. 1341, November 10, 1883; settlement made in spring of 1883, 160 acres; desert filing No. 633 in 1883; number of acres proved upon three years afterwards, in summer of 1886, 440 acres.

5. How many acres are now under cultivation?—About 400 acres.

6. By what ditch or ditches is it watered?—By Labonte Road Ranch Ditch No. 1 and Labonte Road Ranch Ditch No. 2.

7. From what stream is water taken?—From the main Labonte Creek.

8. Give history of construction of ditches.—Labonte Road Ranch Ditch No. 1 was begun in 1880 and partly completed and water run through it in the spring of 1883, but the ditch and ditch-head was very unsatisfactory at that time, owing to the fact that none of the excavation was "down to grade" and would only carry water during a "stage of high water." At this juncture my associate and myself purchased the ditch and entire ranch property and all improvements, paying $5,000 in cash for same. The parties we purchased from had made no land entries up to that time, but they were about to do so. Since the date of our purchase in 1883 we have enlarged No. 1 ditch, put it "down to grade," and kept it in constant repair at a very heavy annual cost, and it is now a permanent ditch, as all banks are grass grown.

Labonte Road Ranch Ditch No. 2 was commenced in the fall of 1883 and work has been done constantly upon it up to date, and the ditch has been in operation about one-half the time since the spring of 1885, and it is now in perfect order, but requires constant labor at a heavy expense to keep it in condition.

(*a*) Name of owners—Charles A. Pollard and Sophia E. Pollard.

(*b*) Date begun and time occupied in building—1880 and 1883. All of two years and three years.

(*c*) Dimensions—5 by 2 feet; length, about 12 miles; depth, 2 feet; width, 5 feet on bottom, 8 feet at top.

(*d*) How many acres does it water?—The two ditches will water more than 1,500 acres.

(*e*) What was the cost of construction?—The original cost per mile was over $250 per mile at a rate of 16 cents per cubic yard for earth; 25 cents per cubic yard for gravel; 35 cents per cubic yard for bowlders and all loose stone; $1 per cubic yard for all solid rock. Since the ditches were completed it has cost double the above amount to maintain them and to repair them.

(*f*) What is the cost per year for management and repair?—All the way from $50 to $150 per mile, according to the number of "water spouts" and "cloud bursts" that happen to strike the banks.

9. Do you buy or sell water? If so, state price paid or received.—We have sold some water at $1 per acre per annum for land actually irrigated during the season. We have also sold some other water at about the same rate.

10. Have you all the water needed?—Yes, during the irrigating season.

11. What is the usual cost of bringing wild lands under cultivation? This to include plowing, grubbing off sage brush, fencing, etc.—Anywhere from $10 to $25 per acre. Any kind of reclamation will cost $10 per acre.

12. How many years are required to bring "wild land" into a proper condition for farming?—From three to six years, according to the sage brush, alkali, prickly pear, and general character of the soil and "lay of the land." If very gravelly and sandy it requires time for the sediment or wash in the water each spring to flow out upon the sand and gravel and form a soil that can not be excelled by any known process of fertilization. Say six years for this latter kind of land, and after the six years I firmly believe the land could be successfully cropped to the same product each and every year forever, as the soil is constantly renewed by the rich sediment or wash that comes down the stream with the spring freshets.

13. What did it cost you to prove up and obtain title to your land and what was the length of time required? If any difficulties were encountered state what they were?—I made final proof upon my land entries under very great hardships, such as travel overland through heavy snows and storms more than 138 miles to the then nearest land office, viz, Cheyenne; at great expense for road ranch bills en route for myself and witnesses, and, as all the witnesses were taken from their daily labor at their homes, I naturally had to pay them for the time consumed going to and coming from Cheyenne land office. My pre-emption proof cost not less than $400, my desert proof cost not less than $640. This includes the money paid to Government and cost of time paid for, and cost of transportation of all witnesses to Cheyenne land office and return, and advertising land proof, and expense en route and at Cheyenne. I was also subject to a four days' delay at Cheyenne after we had supposed the officials were all through, by their demanding a "copy of my marriage certificate," which at that time was hard to procure. As yet I have no land title other than the final receipt. It took about three years.

14. What has your cultivated land cost you per acre?—Not less than $20 per acre for the best, and all of it has exceeded a cost of $10 per acre.

15. What is the present market value per acre?—No land in this part of the country having changed hands at any price for a long time, owing to the uncertainty of our ever seeming to be able to secure titles and a consequent depressed state of affairs with all land entry men, it is impossible for any one to state any price with any kind of certainty, but I should judge any land thoroughly reclaimed and under a ditch to be worth $30 to $40 per acre.

16. Can you raise crops without irrigation?—No, most assuredly. No one can raise a crop or anything like a crop without irrigation, and after a residence of twelve years I have yet to see the crop raised without irrigation any where in Wyoming, and I have tried each and every season for twelve seasons. The trouble with our fair Territory is, that all the reports about raising crops without irrigation are made by the ever increasing majority of new-comers who are always welcome to our arid land, but with them the wish is "father to the thought" or rather belief (for they honestly believe so), for about all sections of our Territory put on a "splendid mantle of green" along in April and May, each year, but in June and July it all turns to a "golden yellow" invariably long before maturity.

It can not be termed a drought for it is the rule and not the exception; perhaps once in five years or once in three years a few potatoes or a small garden can be grown or partly grown without irrigation along some mud bar or bank, too, or island in the stream, but all such crops or so-called crops are irrigatad naturally and not grown by rain-fall by any means. During the year 1883 a good crop could no doubt have been raised by rain-fall in certain parts of Wyoming. But as the farmer can not possibly tell in advance what the rain-fall for the coming season will be, and as whenever there is sufficient rain-fall it only happens once in five years, it is utterly impossible to depend upon anything other than artificial irrigation, except in some of the mountain parks where there are such heavy winter snows that they melt very late in the spring and the ground there stays moist until after the middle of July, but here the crops fail, too, as often as they succeed.

17. Do you think the present land laws adapted to the conditions of the Territory?—No, I certainly do not think the laws are adapted to the conditions of our Territory or to anything like it to a small degree.

Among the changes I would suggest are, to allow each individual, reclaiming land in a bona fide manner, to enter 2,000 acres or less. This amount should be so allowed him to secure the cost and maintenance of the ditches and as an incentive to build the ditches. In other words, give title to 2,000 acres or less of good irrigable land as a premium to any one reclaiming, in order to partly re-imburse the entry man for the extraordinary cost of, and what is more important the maintenance of the ditches in the future years.

Let the State or Government officials determine by actual survey all the worthless hill-tops and other lands lying too high and rough to ever have water conducted upon them by any means, and when this fact is positively ascertained allow the entry man as a free gift five acres (of all such worthless land and hill-tops lying adjoining to his good irrigable land) for each and every acre of land actually reclaimed, provided such worthless land must lie adjoining his 2,000 acres or less of irrigable land, on each side or along on one side and provided further, the entry man to pay Government the real cost of all such surveys. Also to allow all companies or corporations each alternate section of land (along under any ditch or canal) actually reclaimed by said company or corporation.

I am aware that the changes suggested by me as above will be looked upon with suspicion by some good people, but it must be remembered that these good people know nothing at all about what is really necessary to a successful reclamation of our arid Territory, and it is, to say the least, very unfair that they should have anything at all to say in the premises until after a residence of three to five years, engaged at an actual effort to cultivate the soil.

As the land is, in its natural state, it must lie forever worthless for ages. By a liberal policy, and allowing land enough to be entered to make it an inducement to capital to reclaim it, poor men will be constantly employed, and by their employment will be able to subsist and carry out in their turn their own plans and land entries on a smaller scale and in accordance with their means, whereas, as it now is, the poor man must obtain employment from some source or fail in his land entry entirely, as witness the many changes from one entry to another entry upon the same piece of land without attempting to prove up at all, thus exhausting two rights upon really one entry. And then, too, without any assurance that they will be any better able to prove up at the expiration of the second entry.

Allow no alien to enter any land until he has been a law-abiding citizen for five years, but allow any alien to acquire any lands by purchase from citizens, if he continues or keeps up the reclamation of such land by water.

Allow no contests for the right to enter lands or for the possession of title to same under any circumstances until three years after the original entry man had either failed to prove up or had really and actually abandoned his claim. Let all parties who have acquired a so-called title to land or any kind of a pretended possessory right whatever to improvements thereon or to the land or any part thereof "by contests" without first recognizing the original entry man, be forever barred and deprived of all their land rights as now existing or that may hereafter exist under the laws of our country.

I would modify the present land laws as they now stand by not requiring any actual residence upon any of them, but in lieu thereof insert a clause making the reclamation of all of the rights to lands by water compulsory, and not require any actual residence upon any of the claims where they had been honestly reclaimed with water. By honest reclamation of the land is meant the ownership by purchase or of appropriation of about 1 cubic foot flow of water per second of time for each 100 acres during the irrigating season, viz, during the months of May, June, and July, each year.

The central and best part of our Territory is traversed for its entire length by the "old Mormon trail," made when they left Nauvoo, Ill., more than forty-four years ago. Here, over the same old route, the California gold-hunters first traveled. Also the pony mail, and then the telegraph line to San Francisco, and afterwards Wells, Fargo & Co.'s overland stages.

The hundreds of mountain streams and small watering places, all crossed by this trail, all bear the plainest kind of evidence of having been quite thickly settled more than thirty years ago—old wells and old cabin foundations and stone chimneys all gone to decay, places where they had plowed for gardens and for grain, and some of the streams have from twenty-five to fifty graves scattered along their banks. There is almost any amount of evidence that Wyoming from the east to the west, through its entire length and best part, was all at one time fairly well settled upon its many streams more than thirty years ago. The question naturally arises why did not these old settlers stay upon their lands if crops can be grown without irrigation?

There are quite a number of people living in the Territory to-day who have been here from thirty to forty-five years, and it will be found upon investigation that all these old settlers have made their living in many other ways than by cultivating the soil. It is very doubtful if a resident of Wyoming can be found to-day who has, strictly speaking, taken his living from the soil for from three to five years, either with or without irrigation. They have all been trappers, hunters, employés of the Government, or had cattle, horses, or sheep, have been miners or freighters, any and everything other than tillers of the soil. The many hundreds of "deserted hearthstones" scattered all along the many water-courses of the Territory everywhere ought to convince the most skeptical that the desert-land entry man of to-day is right, and that our wise land-law-makers at Washington made no mistake on the side of liberality. The fact stands forth patent to all who are willing to make observations of the plainest character, that to remove our desert-land entry men and the cattle industry from our midst the Territory must go back and become comparatively deserted again by its people as it once was thirty or forty years ago.

Should the Government allow the entry man 2,000 acres of the best irrigable land at each filing, it is very doubtful then if the entry man would have anything like 500 acres of available land for cultivation. Will any one say it is right and justice to allow 480 acres of good agricultural land to be entered in the humid regions under the three old land rights of homestead, pre-emption, and timber-culture, and not allow an equal amount entered in the arid region? The entry man in Wyoming should have four times as much land as elsewhere.

18. What should be done with the grazing land which can not be irrigated; what is the value per acre?—All grazing lands and other worthless lands adjoining any good irrigable land actually reclaimed should be given to the land entry man adjoining at the rate of 5 acres of all such grazing land for each and every acre of irrigable land actually reclaimed by said entry man, provided the entry man pays the Government the actual cost of survey of such grazing land. The balance of the grazing lands that are left upon the hands of the Government should be leased to the highest bidder for cash for a period of five to ten years, with the privilege of a renewal of the lease at its expiration at the same rate if desired and there is no higher bid meantime. Grazing lands are worth from 5 to 50 cents per acre, and there are thousands of acres of such land that are entirely worthless and will probably always remain so, owing to their sterility and roughness.

19. How do you regard the withdrawal of all public lands from settlement during the irrigation survey?—If the lands can be restored to entry under our present land laws again after they are so withdrawn or after the irrigation surveys are completed I certainly should be very much in favor of withdrawing all lands from entry, or if the lands can be restored to entry under a more liberal system of laws than we now have, I certainly should favor the withdrawal. But if they can only be restored to entry under the homestead law, and that, too, with a new requisite for an actual residence of seven years, I certainly should think it unwise to add that increased hardship, and should not by any means favor their withdrawal in the last case. The desert-land law as it now stands is by far the wisest law ever passed by Congress, not excepting any of them, and it should not be touched at all unless to allow more access to the entry man and the land to conform in a body to the entry man's ditch as regards grade of ditch.

We have in the "far West" a very large class of migratory citizens who do nothing but travel overland from some of the older States to Washington Territory this year, and from there to Montana the second year, and from Montana to New Mexico the third year, and so on, the greater part of their lives. Constantly on the move, over thousands of miles of wagon-roads, and they subsist upon and live off the broad generosity of their settled countrymen generally. If they do happen to settle down upon a claim they do not as a rule stay longer than six months or a year. This class would certainly give the Irrigation Survey trouble if the lands were open to settlement by coming in by the thousands to get a location long before the Government was ready, and this is the class, too, that gives the honest entry man any amount of worry and vexation by always putting in an appearance and wanting no other land only such as has been filed upon in good faith, and also by writing constant complaints to the officials at Washington.

It is my belief that for every bona fide settler now occupying public lands there are twenty-five of this migratory traveling class, on the move. And if, as is said to be the case, the Eastern people generally are opposed to the rapid settling up of the West, I beg to respectfully call your attention to the state of affairs all over the far West.

In a country where less than seven years ago was an entire vast wilderness from old Mexico to the British possessions and from the Missouri River to the coast, with the exception of a narrow strip along the Northern Pacific Railway and small parts of Texas and Colorado. I repeat that a very short time ago all, or about all, of this vast stretch of country was uninhabited except by Indians and some military posts, and is now completely overrun with people and towns, cities, and villages, railroads, civilization, and the honest settler can be seen upon any stream, brook, and little spring of water, go where one may, all over this vast far West. Oklahoma is a case in point, viz, 10,000 settlers to 10,000 land entries.

Let me say that the land legislators of our beloved country at Washington have made no mistake in so far as they have got. They certainly "builded better than they knew," but as applied to this arid country they did not go far enough. They certainly were not liberal enough. In other words, the wise and liberal provisions of our generous land law-makers at Washington could hardly be broad enough and liberal enough, so long as the many wide gates of our Castle Garden stood for so many years wide open to all the world.

Let us shut them up tight before it is too late, and bar them shut, too, with the strong bars of protection, and remember the old principle of "first come, first served." If by any chance any of our land entry men should acquire too much land, the evil of it is imaginary, as it will cure itself if let alone, and as soon as they have acquired title they will dispose of it reclaimed. Unreclaimed, it will never be disposed of or benefit any one.

If the desert-land entry man made any mistake at all it was in not stopping to consider the value his capital and vast labor would give to a hitherto lot of worthless land, and consequently came a grand rush of people to all try and do the same thing in a country where for more than thirty years, the Government at Washington had asked the oft repeated question of what shall be done to cause the arid country to become an agricultural country, and at last, after many repeated inquiries and long years, the cattle industry has answered that question and answered it fully, and as a man naturally loves the country where he has succeeded in gaining a competence so the capital was forthcoming to build the irrigation ditches and canals. But it must not be forgotten that Bill Nye spoke the truth when he said, "It takes a great many acres of thin grass to make a fat beef steer," and it also requires large capital and any amount of the hardest kind of labor to reclaim desert land.

20. Do you favor the donation of all irrigable public land to the Territory?—Most assuredly I do favor the donation of all irrigable public land to the Territory, for then we should all stand some sort of a show of having justice done to a long-suffering and most patient lot of land-entry men the world has ever known. If the Territory owned all the lands the Territorial officials would (no matter of what political party or creed) be the judges of our wants and needs, and we should stand a fair show at least; whereas now the average man from any other section of our country knows nothing at all about our wants and seemingly can't be made to understand us, and really he can't be expected to help us until after a residence of from three to five years, trying to reclaim some of our arid lands and then, when he is won over (as they all are), his voice is drowned too by the ever-increasing majority of new-comers.

Incorporated Water Companies of Wyoming.

[Furnished by the secretary of the Territory.]

Name.	Principal office or place of business.	Date of incorporation.
The Wyoming Ditch and Water Company	Cheyenne	July 9, 1869
The Laramie Water and Ditch Company	Laramie	Mar. 27, 1871
Do	do	Sept. 12, 1874
The Albany County Ditch Company	do	Oct. 1, 1874
The Big Laramie River Water Company	do	Apr. 28, 1875
The Evanston Ditch and Water Company	Evanston	July 27, 1878
Pioneer Canal Company of Albany County, Wyo	Laramie	Apr. 22, 1879
Laramie River Ditch and Water Company, No. 1	do	June 19, 1879
The Rocky Mountain and Bear River Ditch Company	Almy	Aug. 19, 1879
Union Ditch and Water Company, of Albany County, Wyo	Cheyenne	Jan. 8, 1881
The Jack Creek Irrigating Company	Warm Springs	June 14, 1881
The Utah and Idaho Land and Irrigation Company	Evanston	Dec. 23, 1881
Hurlbut Creek Ditch Company	Johnson County	Jan. 25, 1882
The Upper Goose Creek Ditch and Irrigating Company	do	do
White and Jackson Creek Ditch Company	do	Mar. 8, 1882
Big Piney and Prairie Dog Ditch and Tunnel Company	do	Apr. 3, 1882
Trabing Creek Ditch Company	do	Aug. 14, 1882
North Piney and Prairie Dog Irrigating Canal and Tunnel Company	do	Aug. 21, 1883
The Wyoming Five-Mile Ditch Company	Bingham	Aug. 23, 1882
Upper East Side Goose Creek Ditch and Irrigating Company	Johnson County	Nov. 13, 1882
Chugwater Ditch Company	Cheyenne	Dec. 9, 1882
East Side Ditch and Irrigating Company	Johnson County	Dec. 11, 1882
Wyoming Development Company	Cheyenne	May 17, 1883
Helman Ditch and Irrigation Company	Laramie County	June 18, 1883
Wyoming Development Company	Cheyenne	Aug. 10, 1883
Rutledge and Hellman Ditch Company	do	Aug. 21, 1883
The North Platte Irrigation and Ditch Company	Fort Collins, Colo.	Sept. 22, 1883
Goshen Hole Ditch Company	Cheyenne	Oct. 3, 1883
The McKuen Ditch and Reservoir Company	do	Oct. 5, 1883
The North Platte Irrigation and Ditch Company	Fort Collins, Coloe	Oct. 12, 1883
Little Horse Creek Irrigating Company	Cheyenne	Nov. 1, 1883
Bordeaux Ditch Company	do	Dec. 29. 1883
The Deer Creek Canal and Improvement Company	Laramie	Jan. 15, 1884
Prairie Dog Water Supply Company	Sheridan	Jan. 19, 1884

The Crown Ditch Company	Buffalo	Apr. 5, 1889
The Mammoth Canal and Improvement Company	Green River	June 10, 1889

STATEMENT OF STEPHEN W. DOWNEY, OF LARAMIE.

With the mass of statistics before you, it is hardly necessary that I should dwell upon the practical benefits of irrigation, as that point has been fully examined by your committee; but I desire to suggest some plan of action in reclaiming the vast areas of sterile lands in the Rocky Mountain region and on the plains to the east of it.

Government land is becoming scarce, and it is a serious question what to do with our surplus population and how to preserve the equilibrium between the thinly and thickly settled portions of our common country. The nations of the Old World have been compelled to resort to vast and expensive schemes of colonization in order to provide for the excess of their population, and it will be but a short time, probably before the twentieth century arrives, when this question must be met by the Congress of the United States, as we have but little vent for our restless and enterprising population. The only solution is to render available the vast domain which at present lies sterile and useless to the home-seeker, who can not have means sufficient to secure water for the thirsty soil, which he could cultivate and upon which he could establish his home. I believe it to be the duty of Government to assist him and those who will accompany him in finding a home and in the consequent development of the country. There is surely sufficient warrant in this action, as Congress has for decades expended vast sums of money in the improvement of rivers and harbors, in protecting the lands adjacent to the Mississippi River from overflow, in providing for the reclamation of swamp-lands, and in a multitude of directions.

Either one of two plans should be adopted.

(1) Congress should appropriate yearly a considerable sum of money to the purpose of establishing reservoirs, diverting useless waters to streams where irrigation is practicable, and take upon itself the reclamation of the arid lands. Where the streams have deep beds and precipitous banks, and where the land through which they flow can not be made susceptible of irrigation, the waters should be diverted to streams and sections where the water can be made available for irrigation. If this plan be adopted, the Government could part with its lands at an enhanced price, covering the outlay and a reasonable compensation over the cost of constructing reservoirs and maintaining a system of reclamation, and thus recoup the amount expended.

(2) If this plan is not deemed feasible, the lands should be donated to the State, Territory, or county within whose limits the same are, for the purposes of reclamation, with authority to issue bonds for reclamation purposes, to be paid from the proceeds of the rental or sale of these lands, under a maximum and minimum price.

In either of these cases, so far as is possible, the purchase of lands by any one individual, association of persons, or corporation, should be limited in extent, and safeguards should be established, which shall prevent the absorption of these lands by speculators. This limit should not be less than one section of land for agricultural purposes, with a larger area for grazing purposes.

I can not imagine any other methods by which this great domain can be settled and its settlers made prosperous. There will always be a home market for the products of the soil, and with the increase of our population the surplus will all be needed at home.

The great stride in the right direction made by the passage of the homestead law would be supplemented by this step. We must do something to satisfy the land hunger of the people. It is conceded that the most intelligent, prosperous, and valuable portion of our communities is the farmers. What the peasantry is to France, its great conservative and moral class, the tillers of the soil are to this nation.

The rapid increase of population at our commercial centers, composed largely of wage-workers and those who are dependent upon the employment of others, creates a class which, being dependent, will be discontented and subject to the wind of doctrines and the appeals of doctrinaires, and the stability of our Government and the permanency of our institutions and the preservation of our Government must rest in the future, as it has in the past, with the agricultural classes of the country. While all branches of the industries have been protected by Congress and guarded to the utmost by the Government, the great farmer class of the country have received but little aid compared to the efforts which have been put forth on behalf of the commercial and manufacturing interests of the country.

The present time is most propitious for this undertaking on behalf of the Government, and it is but in harmony with the generosity of the Government towards the people of the Territories. A continuation of this policy would achieve grander results and afford an outlet to our rapidly-increasing numbers, increase our wealth and the prosperity of the country, and found in the shadows of the mountains a mighty empire, whose sons in time of war would defend their generous mother with their service, savings, and blood.

ADDITIONAL STATEMENT OF CHARLES H. BURRITT

[As corresponding secretary for Johnson County Mr. Burritt prepared the following for the Territorial Board of Immigration. It was submitted to the committee and ordered filed:]

Only a few years ago agriculture in Johnson County was not considered an industry worthy of consideration. This was the fact in 1881, as the following figures of assessed valuation for that year show:

Cattle in 1881	$1,047,688
Lands in 1881	34,485

The great distance from railroads and the demand for vegetables and grain for home consumption forced the people to experiment with crops. The result was startling, and the sequel was that the business of farming became a leading industry within the next five years. Land "proved up" in Johnson County is assessed for taxation at a value of $3 per acre, including improvements. It is easily worth an average of $10 per acre. The following table of values from the assessment roll of lands shows the increase from 1881 to 1887 in farming lands:

1881	$34,485	1885	$166,032
1882	51,195	1886	229,644
1883	66,160	1887	485,439
1884	147,785		

The real taxable value of this taxable land is at least three times this amount, or in 1887 $1,456,317, which is $408,649 more than the value of the cattle in 1881.

But one-fifth of the lands in Johnson County susceptible of irrigation have been artificially watered. The total area of irrigable lands is estimated at 953,000 acres, and at an average value of $10 an acre would be worth $9,530,000.

The county is in the northern part of Wyoming. Its elevation is only about 4,000 feet. Its streams are more frequent and available than any other portion of the Territory.

It is also one of the best watered counties in Wyoming, being well supplied with innumerable streams heading in the Big Horn Mountains and flowing generally to the northeast and northwest. The water along the foot-hills is clear, cold, sparkling, and soft. The soil is black and sandy loam, and appears to be capable of producing wonderful crops, with irrigation, of any thing that is planted in it.

AGRICULTURAL PRODUCTS.

The agricultural products of the county are wheat, oats, barley, corn, rye, hay, potatoes, vegetables, and fruits. The yields are: Wheat, 20 to 50 bushels per acre; oats, 25 to 75 bushels per acre; barley, 40 to 75 bushels per acre; rye, 20 to 40 bushels per acre; potatoes, 200 to 500 bushels per acre; hay, native blue stem, 1 to 2½ tons per acre; timothy, 2 to 3 tons per acre; alfalfa (lucern), 4 to 6 tons per acre.

The wild fruits are strawberries, raspberries, plums, choke cherries, service berries, wild currants, etc. Tame fruits are strawberries, raspberries, blackberries, currants, crab apples, etc. Strawberries especially grow to perfection. Wheat may be sown in March or April; even that sown in May fully matures three years out of four. In 1887 there were approximately 1,729 acres of wheat cultivated, and the total production was 38,000 bushels, or 2,228,000 pounds. The wheat raised is classed as A1. This cereal is being raised largely in Johnson County to fatten hogs, and even in this way is made to yield a good return. Barley, if sown in early April, can be raised on valley soil without irrigation and of the finest quality. Seventy-five bushels have been raised on an acre. The approximate number of acres in cultivation in the season of 1887 was 345, with a total production of 25,525 bushels, or 1,225,200 pounds. In 1888 a much larger crop was raised.

The malt used by the local breweries is made from home-grown barley and is fully equal to the eastern product. Oats are usually sown in April or May. Oats sown June 20 or 25 have returned fully matured crops of 50 to 60 bushels per acre. While the yield is, as usually, from 25 to 60 bushels per acre, as high as 95 and 105 bushels have been produced. The best crops of Johnson County in 1887, according to location as to valleys, were: Powder River, 37½ bushels per acre on 15 acres; Crazy Woman, 67 bushels per acre on 12 acres; Clear Creek, 65 bushels per acre on 10 acres; Piney, 60 bushels per acre on 25 acres; on French Creek, 75 bushels on 10 acres; on Rock Creek, 70 bushels on 100 acres. The approximate number of acres in cultivation in the year 1887 was 7,861; total production 234,475 bushels, or 8,441,130 pounds. The average weight of a bushel of oats is from 38 to 40 pounds. Corn was the last of the cereal crops introduced in the country. While not the most remunerative thus far it has been successfully grown. The Yellow Dent corn fully matures on our soil, and larger fields are planted every year. As this is the home of the solanum family of plants the potato grows to perfection; it is nothing uncommon to see potatoes weighing from 1 to 4 pounds, dry, mealy, and solid all through. The average yield of the tuber is about 200 bushels per acre; but under favorable conditions there have been 300, 400, and, on rare occasions, 600 bushels per acre raised on ground not manured.

Cabbage grows in very large size and the yield per acre is simply enormous. Heads of 25 and 30 pounds are common; 10 to 15 tons are often raised per acre. Cauliflower is also easily grown owing to the cool nights and the system of irrigation by which the plant can be watered at just the right time to perfect them in growth and development. Onions are an excellent crop, yielding from 300 to 500 bushels per acre of perfect bulbs. The celery raised here is pronounced to be superior in flavor to the famous celery of Kalamazoo, Mich. All other vegetables, such as beets, carrots, parsnips, etc., grow to a large size and yield immense crops. Melons, cucumbers, tomatoes, peppers, egg-plant, broom-corn, tobacco, sorgum-cane, beans, and many other vegetable productions are successfully grown in Johnson County. In 1888, according to thrashers' figures, the oat and wheat crop of Johnson County and Sheridan County was 400,000 bushels; estimated at 350,000 bushels of oats and 50,000 bushels of wheat, which would equal, oats 12,000,000 pounds and wheat 3,000,000 pounds; a total of 15,000,000 pounds or 700 car-loads. The oat and wheat crops of Johnson County alone will equal that amount in 1889. Johnson County can produce equally as good potatoes as Greeley, Colo.

As to the future: If one-third of the irrigated lands of this county were sown in wheat at at an average of 30 bushels per acre it would yield 2,340,000 bushels or 130,400,000 pounds, equal to 7,244 car-loads. If one-third of the area was sown to alfalfa it would produce 192,000 tons annually, and would fatten 58,400 steers, equal to 2,900 car-loads. Not more than one-fifth of the lands of Johnson County susceptible of irrigation have been watered. The possibilities that may be attained when development is complete become enormous. Johnson County will soon have railroads. For its agricultural products there is a ready market in the south.

STATEMENT OF H. B. PATTEN, ENGINEER OF THE WYOMING DIVISION, UNION PACIFIC RAILWAY.

In cases of aridity water is obtained by sinking wells, which, in some cases, are deep enough to be called artesian. Some wells supply large quantities and others only limited. Difficulty is to find water at all under ground; or, when found, to secure quality. Much that is found is extremely poor, being strongly alkaline.

Eighteen artesian wells have been driven, averaging 907 feet in depth. These vary in depth from 300 to 2,300 feet. They cost from $5 to $16 per foot, according to nature of boring, depth, and difficulties experienced, etc. Average cost of those driven is $6,700 per well, or per foot, $7.39.

Of those driven, a total of eighteen, nine are now furnishing fair to good supply for engine use. The other nine are either poor in quality or limited in quantity.

Do not know of any water storage system in use in this country.

Can furnish no direct observations for precipitation, etc., but can refer you to United States Signal Observatory at Cheyenne and to records of observations made at Rawlins by Union Pacific Railway. Subterranean water supply is of not infrequent occurrence. The dry beds of creeks usually have underground flow. The direct appropriation and immediate distribution of water from flowing streams in surface ditches for irrigation is the common and well-nigh only method used.

Irrigation enterprises are common. Large ditches are increasing in size and number. In Wyoming, what are generally known as the Sybille ditch, Pioneer Canal from Laramie River, and Bear River Canal are amongst the largest schemes.

For agricultural purposes water is essential. There are large tracts of land, of very fertile soil, which are now utterly non-producing. Water is the lacking element to the growth of large crops.

STATEMENT OF LOUIS BRECHEMIN, ASSISTANT SURGEON, U. S. ARMY, OF FORT LARAMIE.

For the eastern half of Wyoming Territory it may be stated that farming without irrigation can not be successful and can not be made fairly remunerative under the most favorable circumstances and with the best lands. In looking over this part of the Territory it is at once evident that but a small proportion of the land can receive by irrigation a supply of water sufficient for its needs owing to the fact that the streams are small, insufficient in number and capacity, and so situated that hardly a hundredth part of the land can be utilized. The valleys generally are narrow (the soil in many places sandy) and are surrounded by hills on each side. In order to irrigate successfully, that is, to get the water up on these high lands, it must be brought from a great distance and necessarily therefore at great expense. In consequence of this no combination of small farmers can afford to advance the large amounts required to construct these ditches and an association of capitalists for this purpose is imperative.

In examining the valley of the North Platte River, from the hills to the Nebraska line, it is seen that even in this valley, watered by the largest stream in the Territory, irrigation up to the verge of the banks of the river is necessary in all instances in order to raise crops. Occasionally the native grasses grow in spots, due to subirrigation from overflow of the river when it is high.

In rare instances, on second bench land where the prickly pear is plenty and where these are turned over thoroughly by the plow and left to remain under the fallow, not being disturbed by the harrow, there is moisture sufficient created by them to produce a medium crop. This is known as the sod crop and is always better than the second crop, unless the land is irrigated the second season.

When we take into consideration the high winds so prevalent in this county, the danger to ditches by occasional cloud-bursts, the extreme shortness of the season for anything but bulbous vegetation, &c., it may be stated with justice that the eastern portion of Wyoming is not an agricultural country.

These opinions are not altogether the result of personal experience, but have been formed and strengthened by inquiries made of those engaged in ranching in this section. One of my informants has had twenty-two years' experience and has expended large sums of money in experiments of various kinds during that period.

STATEMENT OF J. A. OLMSTED, CAPTAIN, NINTH CAVALRY, COMMANDING, OF FORT WASHAKIE.

From my experience in Texas, Utah, Kansas, New Mexico, and Wyoming I believe there is very little if any land in the United States that can not be profitably cultivated if water can be obtained to irrigate. When there is no surface water to be obtained wells, common or artesian, will always reach it. But the latter are too expensive for private individuals and will have to be made by the Genenal Government.

STATEMENT OF A. H. JACKSON, CAPTAIN, SEVENTH INFANTRY, U. S. ARMY, OF FORT WASHAKIE.

Information upon the subject of reclaiming waste lands by irrigation, derived from actual experiment and observation, extends little beyond the primitive cultivation of sage-brush lands employed by troops in the Northwest and ranche people in their vicinity.

Land of this character will usually produce good crops of grain and vegetables, with little expenditure of labor after that, of constructing the system of ditches for its irrigation.

In the selection of land, its adaptability to artificial irrigation is, of course, the first consideration. Sage-brush will soon disappear in the process of irrigation alone, which also serves in a large degree to relieve the soil from alkali deposit, provided there be a sufficient incline to carry it off.

A settler will do wisely, however, in avoiding land of the latter description altogether.

I have no practical knowledge of the larger systems of irrigation sometimes carried out in the Northwest at great expense and necessary in reclaiming the arid plains of the Southwest.

STATEMENT OF WILLIAM QUINTON, CAPTAIN, U. S. ARMY, FORT WASHAKIE.

Can only give the result of observation from the management of company gardens in Montana and Wyoming. The result of such observation is—

(1) No one single thing can be raised in the Territories referred to without irrigation.

(2) The soil is very rich, and although the growing season is rather shorter than the east, everything can be raised by means of irrigation.

(3) Ditches ought to be of sufficient depth to prevent the overflow of the soil intended to be irrigated—as the presence in the soil of large deposits of alkaline salts causes, from the action of the sun, over-hardening of the soil if overflowed. However, feeding the soil with a liberal supply of stable compost, coupled with frequent irrigation, will in the course of a few years' cultivation remove these salts.

WESTERN NEBRASKA DIVISION.

OGALALLA, NEBR., *September* 19, 1889.

The committee met pursuant to call of the chairman.

Present: Mr. Stewart, (chairman), also Director Powell.

STATEMENT OF ALFRED HOLLINGSWORTH, OF OGALALLA.

The CHAIRMAN. What is your occupation?

Mr. HOLLINGSWORTH. I am a physician and am engaged in farming.

The CHAIRMAN. How long have you resided here.

Mr. HOLLINGSWORTH. Since the spring of 1885.

The CHAIRMAN. What do you say as to the sufficiency of the rain-fall to produce regular crops here?

Mr. HOLLIGSWORTH. My experience has demonstrated to me that it is entirely insufficient.

The CHAIRMAN. You do occasionally raise crops here I suppose?

Mr. HOLLINGSWORTH. In certain localities, where local showers happen to come at the right time. But taking the amount of acres the country over in these parts, the crop is very light.

The CHAIRMAN. Can you mature all sorts of crops here?

Mr. HOLLINGSWORTH. As a usual thing the crop dries out and burns up for want of moisture before it comes to maturity.

The CHAIRMAN. Are you familiar with the State farther east?

Mr. HOLLINGSWORTH. I have seen people from the extreme eastern part of the State. I have traveled about a good deal by private conveyance and have always made inquiry about the crops.

The CHAIRMAN. How far east of here does this deficiency of rain-fall interfere with the regular production of crops.

Mr. HOLLINGSWORTH. I would place it about 100 miles east of here.

The CHAIRMAN. And they sometimes have failures east even of that?

Mr. HOLLINGSWORTH. Yes, two years ago they did have.

The CHAIRMAN. Have any measures been taken here to increase the moisture by irrigation or by the artificial storage of water?

Mr. HOLLINGSWORTH. There is an effort being made at the present time to do that.

The CHAIRMAN. Is there any land under irrigation here?

Mr. HOLLINGSWORTH. No, not in this county. There is irrigation in the western part of Lincoln County, the adjoining county on the east, on the Platte Valley.

The CHAIRMAN. Where do they get their water from?

Mr. HOLLINGSWORTH. From the North Platte River.

The CHAIRMAN. How far is it from here to the North Platte?

Mr. HOLLINGSWORTH. Six miles straight north.

The CHAIRMAN. Is there any irrigation on the North Platte opposite here?

Mr. HOLLINGSWORTH. No.

The **CHAIRMAN**. Nor west of here?

Mr. **HOLLINGSWORTH**. I think not. There is none that I know of.

The **CHAIRMAN**. Did you ever live in an irrigated country?

Mr. **HOLLINGSWORTH**. No; but I have been investigating the water supply for irrigating purposes for the last six weeks or two months.

The **CHAIRMAN**. You have seen no storage of water or any irrigated country yourself?

Mr. **HOLLINGSWORTH**. No.

The **CHAIRMAN**. How have you investigated the question of water supply?

Mr. **HOLLINGSWORTH**. We have been working up an irrigation scheme for the South Platte River here about twenty-five miles.

The **CHAIRMAN**. Is your engineer here?

Mr. **HOLLINGSWORTH**. Yes.

STATEMENT OF L. E. HICKS, OF LINCOLN.

The **CHAIRMAN**. What is your occupation?

Mr. **HICKS**. I am professor of geology in the Nebraska State University.

The **CHAIRMAN**. I presume you are pretty familiar with the State, and have given some attention to the subject of irrigation. We shall be glad to hear any statement on that subject which may be of use to us in our inquiry.

Mr. **HICKS**. I have given attention to the subject of irrigation ever since I came to reside in Nebraska. I have felt a deep interest in it, and have had and now have a very strong conviction of its necessity and importance.

There are certain things that I had prepared to say at Cheyenne, which I will say here, though I will not now say all that I intended to say there, because that place would have been appropriate for certain things which it is not necessary to say now. To a certain extent, however, the scope and direction of my remarks will be influenced by the fact that I prepared to speak at Cheyenne.

I have prepared hastily a map, which may be marked "Hicks, A." All that I did had to be done hastily because I had very short notice. I prepared this map as exhibiting the Platte River and its tributaries, as the main feature of the map, although it includes the whole of the State of Nebraska. The State boundaries are indicated by dotted lines to a portion of Kansas, a portion of Colorado, and a portion of Wyoming. The political divisions are not conspicuous upon the map and I did not intend to make them so.

The **CHAIRMAN**. You regard political and State lines as having nothing to do with irrigation?

Mr. **HICKS**. That is the point I wished to make by exhibiting this map of the State. Political boundaries should be non-existent so far as irrigation is concerned. I do not think I need to dwell upon that after simply stating it and calling attention to the physical features of this region, which emphasize the fact that State boundaries ought not to be considered as having anything to do with the question of where the water is to go or where it is to come from. We ought to consider a certain region (without regard to State boundaries) in its physical aspect as a hydrographic unit.

The Platte River is a remarkable stream in many respects. It is one of the large rivers of the world, considered with respect to its length.

The South Platte rises in the southern part of the Rocky Mountains, and the North Platte in the northern part. Each of those branches of the Platte is an important and valuable stream for irrigation. Not only so, but the numerous tributaries of the North Platte and the numerous tributaries of the South Platte are all valuable streams for irrigation.

I do not propose to speak at any length of the South Platte. We have a great interest in the South Platte, and the people of Ogalalla are particularly interested in it, but I propose to speak more particularly of the North Platte, because I think there is more value and more hope for Nebraska in the North Platte than in the South Platte. The State of Colorado includes a large portion of the South Platte. There are about 80 miles of the South Platte in Nebraska. I hope the committee will take a ride across the South Platte, and see it for themselves.

The CHAIRMAN. You may explain the condition and capacity of that stream.

Mr. HICKS. I have not proposed to say very much about the South Platte, as it would take me some time to say about it all that I should like. I should like to say why I believe that in the long run the use of the waters of the South Platte is going to benefit the people along here, because it will fill up, soak up, the lands in Colorado so that the lands themselves will become a great reservoir to gradually and constantly yield waters to fill the Platte along here and all the way down to its confluence with the North Platte and ultimately be beneficial. That, however, would take a long time. It will be hastened by the measures now being prosecuted under the authority of the General Government by the U. S. Geological Survey under the direction of Major Powell.

The taking out of the surface waters—the flowing waters—in the streams during irrigation season has deprived the people here on the South Platte of water, and has been an injury to them by taking the water which otherwise would flow through the South Platte. The beneficial result which is ultimately going to come from irrigation in Colorado will be hastened by this irrigation survey and by the construction of hydraulic works in the places which will be indicated by the survey. I understand that the survey conducted by Major Powell is not to construct anything but to indicate the places where reservoirs for the storage of storm waters may be advantageously placed, and how much it will cost to build the dams and make the reservoirs. I understand the intention is to furnish information so that individuals or companies may do the work.

The North Platte is a stream which has not yet been used up by irrigation in Wyoming as the South Platte has been in Colorado. The North Platte is a larger stream than the South Platte. It possesses many great advantages for irrigation. The whole Platte River in fact presents great advantages for irrigation; in one respect greater I think than any river of the same size in the world, namely its high gradient. For the size of the Platte River it is slow, the amount of fall in it is very remarkable. From Fort Steele away up in Wyoming—not at the head of the North Platte, but within 150 miles of the source of it—down to the mouth, the average fall for the whole distance is over 7 feet to the mile. If you carry the measurement up to the very sources of the Platte, of course it would be much greater, because the upper waters have a steep slope. The slope in different parts of the river vary a great deal, but it may be of interest to you to hear the details of the gradient of the Platte in different portions of it.

From Fort Steele to the Wyoming line the average gradient is 8.6 feet per mile; from the Wyoming line to the town of North Platte it is 7.4 feet per mile. I do not think you can find any other river of that size which has so high a gradient as the North Platte for so long a distance. That is certainly a very high gradient and, you know very well what that means in respect to its value for irrigation. If a stream has very low gradient and you take a ditch from it you have to go a long distance before you can get the water in. From North Platte to Kearney the grade is much less, being only 5.6 feet per mile and from Kearney to Fremont, singular to say, the grade is higher than it is from North Platte to Kearney, being 6 feet. The average for the whole distance from North Platte to Fremont is 5.8 feet.

There are many characteristics of this stream and of the country which it waters which I should like to point out in detail, but I think I have said enough to indicate what admirable provision nature has made for furnishing water to a very large piece of country, and it only needs the guiding hand of man to pour out its beneficent results on these plains to produce values in agriculture which can be expressed only by millions of dollars.

I shall return now for a moment to the subject of this map to illustrate the physical features of the Platte.

The CHAIRMAN. I should like you to state what the topography of the country is on each side of the river.

Mr. HICKS. I had intended to speak of that but do not want to make my remarks too long. If I speak of the lay of the land I shall be getting at that important point with respect to a very large section of Nebraska, and therefore it is perhaps as pertinent here as to speak of it in detail with regard to other streams.

The CHAIRMAN. I should like, if you are familiar with that stream, to have you state the elevations, and the opportunity for getting at the water also the extent of land that could be covered by it, commencing with the point at which you begin with the fall or grade of the river.

Mr. HICKS. With regard to that part of the river that is in the Territory of Wyoming you have had the facts from the engineer of that Territory, Mr. Mead.

The CHAIRMAN. That was as to the deep channel, but you commence where the channel is low.

Mr. HICKS. In the upper, or Wyoming, portion of the Platte a great deal of it flows through cañons, so that the taking out of the water would be difficult, but near the place where it crosses the west line of Nebraska (the Nebraska-Wyoming line) it comes out from the cañons and flows through a comparatively level country; in some places high banks on one side or the other, and on the whole, its valley is deep. The hills, when you get back to the crest, are high all along, but the slope is gradual, especially on the north side. It is no longer a cañon at that point, and therefore it can be taken out for irrigation in western Nebraska and to some extent in Wyoming, on the north side. On the south side there are bluffs all around here.

The CHAIRMAN. How far?

Mr. HICKS. To a distance of 30, 40, or perhaps 50 miles from the Nebraska line.

The CHAIRMAN. About midway between Platte and the Wyoming line?

Mr. HICKS. Yes; between North Platte and the Wyoming line the water can be taken out on the north side. There is one point to which I wish to call attention, which in the end may be a point of very great importance, although it will probably involve engineering operations and an expenditure of money on a very large scale.

Speaking of the facility of taking out the Platte, there are two theories of it. The question is whether it is easier to take it out in short ditches to water the lands that lie at a moderate elevation above the stream, or whether to take it out and carry its waters upon the high plateaus, upon the divides or table lands. If you take it out in the latter aspects, if it is proposed to carry the Platte upon the table-lands north of the Platte, you have to contemplate engineering operations upon a large scale—I will not say upon a vast scale, because in India they take out ditches as long as 500, 600, or 700 miles. To take out the waters of the Platte and spread them upon the table lands would require a ditch at least 150 miles in length, which is a great undertaking and would involve the expenditure of large sums of money, and it could only be done by a great corporation, or by national or State authority.

The CHAIRMAN. State which would be the most economical way in the end, per acre.

Mr. HICKS. To carry it out on the table-lands, or to use it in the valley?

The CHAIRMAN. Yes; which would be the most economical, taking into account the quantity of land that would be benefited?

Mr. HICKS. My conviction on that point is that the proper thing to do is take it out on the table-land.

The CHAIRMAN. Where would you take it out?

Mr. HICKS. I would go as far as the mouth of the cañon in Wyoming—the North Platte cañon, west of the Nebraska line.

The CHAIRMAN. If you had a ditch running out on the north side, explain where it would run?

Mr. HICKS. There is a vast body of table-lands between the Niobrara and the North Platte.

The CHAIRMAN. That river runs nearly parallel to that north line we call the Niobrara?

Mr. HICKS. Yes.

The CHAIRMAN. What is the average distance between the Niobrara and the North Platte, at about the one hundredth meridian?

Mr. HICKS. About 100 miles.

The CHAIRMAN. What length of ditch would it take to run it out at the mouth of the cañon and run it to the meridian?

Mr. HICKS. That would be well on to 200 miles.

The CHAIRMAN. And if you went down to the ninety-eighth meridian you would have something further to go?

Mr. HICKS. About, probably, 320 miles.

The CHAIRMAN. What is the character of the soil on that plateau?

Mr. HICKS. It is excellent. It is of the character which generally prevails upon the table-lands and in all this belt of country. The table-lands have a soil which is very rich in all the elements of fertility and has a subsoil compact enough to hold the water without being hard pan to prevent the water from entering it and being retained by it. It has the necessary porosity to have that quality to a useful extent, without having it to such an extent as to waste water. Therefore in every respect the table-lands are excellent for containing water and for its application to irrigation.

The CHAIRMAN. And for retaining water in the ditch?

Mr. HICKS. Yes.

The CHAIRMAN. They are better for retaining water in the ditch than the gravelly bottoms?

Mr. HICKS. Yes.

The CHAIRMAN. It would be an economical use of water to take it out there?

Mr. HICKS. Yes.

The CHAIRMAN. What do you say as to the quantity of water in the North Platte to supply such a ditch?

Mr. HICKS. I have never gauged the North Platte, and can not speak with any positiveness as to that. Major Powell could inform you better than I can on that subject.

The CHAIRMAN. Have you ever seen the North Platte in flood time?

Mr. HICKS. Yes.

The CHAIRMAN. Is it a large stream, then?

Mr. HICKS. It is an immense stream.

The CHAIRMAN. What would be the opportunity of storing the water to supply such a ditch?

Mr. HICKS. There are good places for storage basins to contain the flood water.

The CHAIRMAN. Suppose you have it on the summit of a ridge, would you be able to make reservoirs to catch the water in flood time as you followed the Niobrara on one side and the Platte on the other?

Mr. HICKS. Yes; there are such places.

The CHAIRMAN. So that you could enlarge the quantity?

Mr. HICKS. You could enlarge the quantity by retaining the waters that fell along the course of the ditch.

The CHAIRMAN. What do you say of the flood waters with which you could augment the stream between the Niobrara and the Platte? Do the rains fall there to a considerable extent?

Mr. HICKS. The rain-fall has never been carefully investigated in that region. The stations for the investigation of rain-fall are none of them so situated as to do that, and it is impossible to say with positiveness what the rain-fall is, but I am safe in declaring that it is certainly 15 inches or over. With that amount of rain-fall you can form an idea of the amount of the flood waters which might be saved.

The CHAIRMAN. What is the character of the surface—has it got basins and ravines and unevenness enough to find storage places or places to catch water?

Mr. HICKS. The topography is extremely favorable for storage. I might perhaps qualify that word "extremely." It is favorable. It is certainly as favorable as the average conditions over the county, if not more so.

The CHAIRMAN. I observe by that map that between the two rivers you have other streams marked.

Mr. HICKS. Yes. Those are the Loup rivers and their tributaries—the whole being tributary to the Platte.

The CHAIRMAN. Have you got on the map all the rivers and ravines that are between those rivers?

Mr. HICKS. No. This map was hastily constructed to bring out certain points especially the point that State lines ought not to come into account. There are many streams that are not on the map. I have not put in any tributaries of the Niobrara River.

The CHAIRMAN. Independently of taking the water from the Platte, which of course must ultimately be done (that would be a great enterprise), what are the opportunities for storing the storm water, to begin with?

Mr. HICKS. Do you mean over the surface generally?

The CHAIRMAN. Over the surface generally.

Mr. HICKS. In my belief the opportunities are good.

Director POWELL. Will you please state a little more fully the advantage of taking the North Platte out upon the divide between the Niobrara and the Platte itself—the advantage of taking it out upon a high line to the region between that high line and the Platte itself?

Mr. J. J. MCINTOSH (of Sidney, Nebr.). I would suggest that the examination be confined to the country west of the one hundredth meridian, as east of that line it is not claimed that it is necessary to have irrigation.

The CHAIRMAN. I think that irrigation is not confined to that meridian any more than it is to State lines. Let us have the facts.

Mr. HICKS. I am going to answer the question, but I wish to get at it by a circuit. The proposition I have made about taking out the North Platte may seem to be a rather startling proposition because of its magnitude, but if it can be shown that there are certain great advantages that can not be secured in any other way, then we will contemplate that proposition.

In answer to a suggestion of Major Powell's, I will bring out one of the things which constitutes a great argument for attempting work on a large scale like that. It is that by taking out these waters upon the high divide here you have them at an elevation above the stream, and with a slope between the main ditch and the stream, which includes a vast body of land—land that is well suited for irrigation, almost every acre of it, and which lies upon this slope between that main ditch and the Platte in such a way as that when you have used the water up here next to the ditch, upon the highest part of that divide, and irrigated your fields there, the same water will come on down and irrigate the fields which lie a little lower, nearer the Platte. Then, after irrigating those fields you take it again and irrigate other fields, and so on, using the water of that main ditch over and over again. That is one of the great advantages of attempting things on a large scale.

The CHAIRMAN. If you had the ditch, need it necessarily be on a very large scale to irrigate some lands?

Mr. HICKS. No.

The CHAIRMAN. And as you extended it along here you would cover a great deal of land with every mile, would you not?

Mr. HICKS. Yes.

The CHAIRMAN. The work done would be a great deal larger as you went along. When you irrigated this land along the ditch and filled it with water, would not that filling of water work along down and fill the land towards the river, saving the water all the time?

Mr. HICKS. Yes.

The CHAIRMAN. And go of itself down towards the river?

Mr. HICKS. Yes.

The CHAIRMAN. And if you were up here on the high divides could you not start your ditches and make reservoirs below it, to save your surplus water and do a good deal more work with it than if you took it out on the low beds; would it not get right back into the river there?

Mr. HICKS. Yes, and there are other reasons why it is not so good. I may introduce some qualifications here. Job said, "Oh * * * that mine adversary had written a book." I wrote a pamphlet about this subject once. I contemplated taking out the North Platte and am in a measure going back on my record.

The CHAIRMAN. Are you familiar with the facts as to how far east the water would be useful if that ditch was extended? I am not putting it at the bare point of necessity where you could eke out life on that land, but how far would it be useful to extend that ditch?

Mr. HICKS. If I should answer that question just as it lies in my mind I should take it out clear to the Missouri River. I maintain that the use of water in irrigation would be advantageous on account of its increasing the yield and making the yield certain, giving you the opportunity to put the water on the land just when it needed it, instead of waiting for the clouds to pour it on. They do not always bring it when it is needed. Therefore, on account of the certainty of the results and of the increased yield of the fields, I say that water for irrigation could be profitably used all over the State of Nebraska, but I do not believe you intended the question exactly in that sense.

The CHAIRMAN. I wanted to know fully where it would be useful.

Mr. HICKS. I will answer it now in another way: "What is the eastern limit of the arid region?"

The CHAIRMAN. What I want to know is where the division line is, if there be one, between poverty and comfort, without irrigation?

Mr. HICKS. I would rather answer it in the form in which I put it, "What is the eastern limit of the arid region?" My conviction is that so far as you can define the eastern limit of the arid region by mathematical lines the boundary is the one hundredth meridian.

The CHAIRMAN. In Nebraska?

Mr. HICKS. Yes, in Nebraska. I would limit it a little more yet. I would say in central Nebraska. In central Nebraska the one hundredth meridian is the limit. For instance, in Custer County the one hundredth meridian runs right through the western part of that county. Good crops can be raised in central Nebraska up to the one hundredth meridian, and very fair crops in some districts even west of the meridian. Custer County is crossed by the one hundredth meridian, cutting off about two tiers of townships from the west line.

The CHAIRMAN. To what meridian does Custer County extend eastward?

Mr. HICKS. It extends east to about 99° 30′, and that county which lies there mainly between the ninety-ninth and the one hundredth meridian extending over west of the one hundredth meridian took the first premium for county exhibits at the State Fair of Nebraska which has just closed.

The CHAIRMAN. Do you know where those exhibits were obtained; in what portion of the county?

Mr. HICKS. Somebody here will be better able to give you that information, but I will say that in regard to the character of Custer County it is in the Loup River country. Several Loup rivers pass through it, and along those rivers the bottom-lands generally are sandy and poor. The good land is on the divides between the rivers. These divides or table-lands between the rivers occupy by far the greater portion of the county. It was on these divides that the crops were raised that took first premium and therefore upon land which is the prevailing and characteristic land of Custer County and not upon select patches of remarkable fertility, or upon land any more fertile than the rest of the county. So that it is not like the case of crops raised in some particular portion of the county which was a great deal more fertile than the rest.

The CHAIRMAN. Do you know whether that county has had uniform crops for a series of years?

Mr. HICKS. Custer County is new; the oldest lands in that county (those that have been plowed the longest) have probably not been plowed more than five years, and during that time the yield has been uniformly good. The first plowing of those lands does not yield the best crops as it does in other parts of the country.

The CHAIRMAN. Are you familiar with Brown County? If so, what can you say as to the land there?

Mr. HICKS. The land in Brown County is not very good.

The CHAIRMAN. How is it situated as to rain-fall?

Mr. HICKS. The rain-fall is not perhaps quite so great, because the lines of greatest rain-fall do not pursue mathematically straight courses, but make curves. The line of greatest rain-fall would be something like this [indicating upon the map].

The CHAIRMAN. Commencing at the southeast corner of Harlan County?

Mr. HICKS. Yes, and passing out here to the one hundredth meridian and curving off.

The CHAIRMAN. Commencing at the southeast corner of Harlan and then going in a northwesterly direction, crossing the Platte River at the western part of Dawson, and then continuing north to Custer and Brown about on the one hundredth meridian, and when it strikes Brown it would then be a sharp angle to the east through the corner of Brown and Holt up into Knox County and to the Missouri River. That would be about the line of equal precipitation, according to your observation?

Mr. HICKS. Yes; and therefore the boundary of the arid region would not be the mathematical line of the one hundredth meridian according to my opinion, but the line of equal precipitation would be a curve and not a straight line. Westward of that line irrigation is needed.

The CHAIRMAN. Is it a necessity?

Mr. HICKS. It is not an absolute necessity in many portions.

The CHAIRMAN. Is it a necessity to general prosperity?

Mr. HICKS. Yes; it is a necessity to general prosperity and highly advantageous for the certainty and the greatness of the yield which would result from irrigation—the certainty of a production of a fair crop and a greatly increased yield per acre.

The CHAIRMAN. About what proportion of the State would that take—about one-half of it?

Mr. HICKS. Something more than one-half.

The CHAIRMAN. Then something more than one-half is in the arid belt?

Mr. HICKS. Yes; about one twenty-fifth of the whole arid region of the United States is in Nebraska. I want to emphasize that fact to this committee, that Nebraska is entitled to attention in this matter, and we are very glad that you came here to Nebraska to look into the subject.

The CHAIRMAN. In addition to the large ditch that you have suggested, what other modes would you suggest for supplying this arid region with water?

Mr. HICKS. Before leaving the question of the large ditch north of the North Platte I want to say that the water can be taken out on the divide south of the North Platte also. I say that particularly for the benefit of people who are interested on the south side of the North Platte rather than on the north side. Your inquiry now is with respect to additional methods.

The CHAIRMAN. What other streams or means beside the North Platte could be used for irrigation?

Mr. HICKS. It would take me a long while to detail them.

The **CHAIRMAN.** I do not want them in detail. How is it in regard to the Niobrara; is that useful?

Mr. **HICKS.** Yes; I will speak somewhat fully of the Niobrara with your permission, and then more briefly as to the other streams, because what I say of the Niobrara will apply to many others. The Niobrara River carries quite a large volume of water. I never gauged it low down, but away up here in this region—in the northwest corner of the State—I found about 125 cubic feet per second.

The **CHAIRMAN.** At what season of the year?

Mr. **HICKS.** About this time of the year two years ago, at nearly the driest part of the year.

The **CHAIRMAN.** How is it about the wettest parts of the year?

Mr. **HICKS.** I never gauged it then, but I know it carries an immense volume of water.

The **CHAIRMAN.** Has it been utilized at all for irrigation?

Mr. **HICKS.** Not to my knowledge.

The **CHAIRMAN.** What is the character of the country along the Niobrara on both sides? That river would irrigate some lands in Dakota, would it not?

Mr. **HICKS.** Near the north part of Cherry County it might possibly be used in Dakota, but there is a great body of land which might be irrigated by the Niobrara River in Nebraska—in that portion of it which lies in Cherry, Sheridan, Dawson, and Sioux Counties. Below that, for instance in Brown County, the Niobrara River flows in a cañon, and can not be used.

The **CHAIRMAN.** You would have to rely on the Platte and the smaller streams.

Mr. **HICKS.** Yes, but below the Platte the facilities of the Niobrara River are excellent.

The **CHAIRMAN.** What is the character of the land and the topography?

Mr. **HICKS.** The land there lies sloping up with a gradual slope from the Niobrara River on both sides all through the counties I name, so that the water taken up by ditch upon that slope could be used between the ditch and the river with the greatest possible efficacy.

The **CHAIRMAN.** What is the grade or fall of the river?

Mr. **HICKS.** The Niobrara has a much steeper grade than the Platte. It is a smaller river, and would be expected to have a steeper grade. The characteristic of the Platte River is its remarkable gradient. For a medium sized or small stream the Niobrara River is remarkable for having a high gradient. I will remind you of the French name of the Niobrara River as you have seen it on the old maps, *L'eau qui cour*, the water that runs. The swiftness of the stream so impressed itself upon the French *voyageurs* that they called it "The water that runs." That of course depends on the grade. It has a high gradient and low banks. The water can be easily taken out. The land lies favorably, and in every respect it is an excellent stream for irrigation.

The **CHAIRMAN.** In addition to that, the different forks of the Loup extend up into Brown, Cherry, and Holt. Can the waters of the Loup be utilized?

Mr. **HICKS.** Undoubtedly. They are good streams for irrigation.

The **CHAIRMAN.** Into what does the White River discharge its water?

Mr. **HICKS.** Into the Missouri in Dakota.

The **CHAIRMAN.** What kind of a stream is it?

Mr. **HICKS.** The White River is not so good in irrigation time as the

Niobrara. Some of its tributaries for small streams are excellent. The White River, however, in the main stream is not so good a stream for irrigation. But on the whole, taking the Upper White River and the tributaries of the White, there is a large body of land in upper Nebraska which could be irrigated. A stream which is one of the very best in the State of Nebraska for irrigation is the Republican River and its tributaries.

The CHAIRMAN. Where is that?

Mr. HICKS. In the southwestern part of Nebraska. As far east as irrigation is needed the Republican River is a source of much water for irrigation.

The CHAIRMAN. In what State does the Republican River rise?

Mr. HICKS. In Colorado, but very near the State line. It flows into Kansas. The Republican, therefore, is a Nebraska river. It is not a mountain stream. It rises on the plains not far from the Nebraska line in Colorado.

The CHAIRMAN. Does it carry water in the dry season?

Mr. HICKS. A great volume of it. I gauged it in Furnas County and found 570 cubic feet.

The CHAIRMAN. What is your theory as to the remarkable supply of water in the Republican—it does not come from the immediate rain-fall does it?

Mr. HICKS. I am not able to say with any positiveness that there is any other important source.

The CHAIRMAN. I have heard it suggested that it was probably supplied from underground water; water that was passing through Colorado under ground.

Mr. HICKS. I think it is probable. Observe what I said, that I am not able with any positiveness to ascribe any other source for the water of the Republican but the rain-fall of the region which it drains. I know that the rain-fall on the Republican basin furnishes most of the water that runs into the Republican. Whether there is any other source of any considerable importance (while I think it highly probable) I do not know any facts that would give me any means of making a positive statement.

The CHAIRMAN. A considerable country could be irrigated by that?

Mr. HICKS. A very great area could be irrigated by the Republican and its tributaries. While I described the land along the Niobrara as lying favorably for irrigation, I think that I could speak with more emphasis still of the land of the Republican. It lies admirably to receive the water.

The CHAIRMAN. As to the South Platte; you have about 80 miles of that in Nebraska. Can a supply be obtained from that; and, if so, how? You have already explained that, by natural process, if the water is stored above, so that it will fill the soil, it will naturally work along down and finally benefit Nebraska; but, not waiting for that, is it possible to take out the water from the South Fork?

Mr. HICKS. I do not want to monopolize the business of giving information to this committee; and, while I might have something to say on that point, the engineer who is now constructing a ditch to take out the water of the South Platte, in this immediate locality is here, and I should like you to ask him that question.

The CHAIRMAN. I wish you would speak at greater length of the storm-water and the facilities for utilizing it in Nebraska generally, according to your observation, by reservoirs?

Mr. HICKS. Do you mean the flood-waters of the streams, or the precipitation upon the general surface?

The CHAIRMAN. Upon the general surface, in the ravines and small streams in the highest portion of the State—anywhere where it could be done without regard to streams. How much of an aid will that storm-water, kept in small ponds and reservoirs, be?

Mr. HICKS. In my judgment it will be of the utmost value; while, compared with many parts of the earth the rain-fall over this region is what you would call light, still, the aggregate of water falling on say a square mile of land in this region, supposing the rain-fall to be 15 inches, can be easily computed; and any one who makes the computation will be astonished at the amount of rain-fall that reaches the land. If the waters that fall on the surface here were collected in small reservoirs, such as might be constructed at moderate expense by individual owners on their own lands, and for the construction of which the topography is favorable, an immense area might be irrigated from these storm-waters.

The CHAIRMAN. How much water do you require in addition to the rain-fall generally in western Nebraska to produce all-around crops? Have you given that particular subject any consideration?

Mr. HICKS. I am not prepared to answer that question definitely as to quantity. I could, however, make an estimate in general terms.

The CHAIRMAN. Do so.

Mr. HICKS. In my judgment, through a large part of the area west of the curve which I have already indicated, the rain-fall and the climatic conditions generally are such that the amount of the artificial aid required from irrigation is comparatively small. For instance, in Colorado it requires 12 inches of water each year on the irrigated fields to produce crops, while, I should say, that in some parts of Nebraska, 2 inches ould be enough, in other parts 3, and in other parts 5, and so on, according to the proximity to this line that I have indicated. Further west, you must have a greater number of inches and during a greater length of time. In many parts west of the line I indicated, if water could be put upon the land only for a few days at a critical time, it would save the crop and make a good crop. So that the amount required varies with the location, and with many local conditions and circumstances. But generally my answer would be, that the amount required is not more than one-third of full irrigation in a great part of this region.

The CHAIRMAN. What effect in Nebraska does thorough cultivation have upon the moisture?

Mr. HICKS. It has the effect of retaining that which falls from the heavens, and of attracting more moisture from the atmosphere in the form of dews, and also probably, locally, in the form of rain. I do not consider it an established fact that the rain-fall of Nebraska is increasing.

The CHAIRMAN. Is it generally supposed that rain-fall is increasing?

Mr. HICKS. Yes; it is generally supposed that it is, and that the rain-fall is traveling westward. As I say, I do not regard that as an established fact; but, owing to the conservation of the moisture in the soil, resulting from cultivation and the protection of the surface by the vegetation that grows upon it, its protection from the heat of the sun's rays, so that it does not become so intensely hot, and so that it does not immediately discharge the water put upon it, the effect of cultivation is manifest. As to the increase of moisture, it comes principally in the form of dew. In the great plains it was often stated and believed by many that there was no dew. In all this region, wherever crops are cultivated, if you go into a field of wheat, oats, barley, or tall grass in the evening you will get your feet wet, and you will find plenty of dew, Where the soil is cultivated and where vegetation is growing there is dew. The reason why there was no dew before cultivation is that the surface, baked by the sun's rays during the day, becomes so intensely hot that at no hour of the night did it become much colder than the air; and the precipitation of dew depends on the condition of a difference between the temperature of the objects which receive the dew (the lower temperature of the earth or of the plants on which the dew collects), than the temperature of the surrounding air. When the surface is protected by vegetation the earth itself does not become so hot—is not so intensely heated by the rays of the sun—and the plants stretching up into the air from the surface of the earth are so situated as to lose their heat rapidly by radiation. As soon as the sun goes down in the evening they begin to cool off, and speedily become colder than the circumambient atmosphere, and in that way form dew. Thus, without any increase in rain-fall, but by the increase in the dew-fall, or the conservation of dew, we have, as a practical result of breaking the surface of the soil, what is the same in effect as if there had been an increase in rain-fall.

The CHAIRMAN. There is another question which I wish to ask you: It has been suggested that by the cultivation of the soil and the production of vegetation over a large surface the rain-fall is equalized and is not so spasmodic and erratic so far as concerns its falling all in a body in a single place as in the case of a cloud-burst. Have you observed in Nebraska any effect of that kind?

Mr. HICKS. Nebraska at present is not afflicted with sudden bursts like that.

The CHAIRMAN. That is, the cultivated portion of it?

Mr. HICKS. The cultivated portion of it. Whether that is due to the cultivation, and whether storms were formerly more spamodic here I am not prepared to answer.

The CHAIRMAN. You have not lived here long enough and observed the changes so that you could not say whether that is a fact or not?

Mr. HICKS. I could not say personally whether it is or not.

The CHAIRMAN. How are rains in this part of Nebraska; do they form cloud-bursts in places, or do they fall pretty evenly over the whole surface?

Mr. HICKS. There are not many "cloud bursts," but there are many local storms.

Director POWELL. What would you suggest as the line of investigation for the arid region of Nebraska?

Mr. HICKS. I believe that the scientific study of the special characteristics of this whole region, pursued long enough and thoroughly enough to give systematic and tolerably complete results, is the proper method of procedure, and in fact the only method, regarding this region as a whole, and that may be done most economically under the authority of the General Government. If it is not so done it must be done at the expense of communities, corporations, or individuals, in a spasmodic, irregular, incomplete, and often inaccurate and inadequate manner; whereas a general survey of this whole region would be in the hands of the most skillful engineers who would present the subject in its completeness and in all its connections, and would be far more valuable in any given locality, so far as it pertains to that locality than if the most thorough survey of that locality had been made by itself.

As to the method of doing that, it seems to me that this region demands a line of investigation different from any other. And when I speak of this region I do not simply mean this portion of Nebraska, or this county, or even this belt of Nebraska in which we now are, or of which I have been speaking, but the whole belt that lies approximately in the same meridian—a belt of one, two or three hundred miles in width, which lies upon the margin of the arid regions, where physical conditions are so different from those which prevail in the mountainous districts that a different line of investigation must be pursued, and a line of investigation which in some respects must be more costly and elaborate than would be required in the mountain regions. There ought to be a great deal of attention given to this region in this Irrigation Survey, and money ought to be expended upon it without stint, all that is necessary to bring out the best possible results.

The reason why it is going to be a more costly survey in this region than in some other parts of the arid regions, is that the streams are inadequate to water this region. While I have described a number of streams for irrigation, I believe I have said nothing beyond what the facts will bear out in regard to the value of those streams; yet, taking them altogether, they are inadequate to the demands of this region for irrigation. You can not get the water out of all the streams in Nebraska to water all the lands that need water here. Nebraska is so happily situated, and its physical condition is so happily adjusted in respect to the character of the surface, that there are very few acres of all this region that are not good arable land. Of all this region that needs irrigation the percentage of it which would not kindly respond to the efforts of the irrigator and farmer is very small, indeed—remarkably so as compared with other regions. We have no mountain ranges. We have a few sand-hills and other places that can not be irrigated. But I suppose the amount of arable land in Nebraska is one-half the land of the State; that is, we will say in round numbers, 40,000 square miles. There is, I should say, not more than 5,000 square miles of that that would not respond to operations to redeem it. We will say there are 35,000 square miles, then, that are suitable to receive the water.

The water of the storms is insufficient to supply that body of land, and therefore the storm waters must be stored in numerous little reservoirs all over the country. To find the places for these numerous little reservoirs, to ascertain the configuration of the surface, and to "place" those reservoirs will take careful and accurate work. In my judgment, the Irrigation Survey should proceed upon those lines in this region to indicate by their careful work where those reservoirs can be constructed, not only how the streams may be used, but how the storm-waters which fall upon the general surface of the country and run off can be saved up and made to water the largest amount of land. In general, that would be my notion of what an Irrigation Survey ought to be for this belt.

The CHAIRMAN. Have you any artesian water any where in the State?

Mr. HICKS. Yes.

The CHAIRMAN. You are aware of the existence of a belt of artesian water in the two Dakotas. Is the artesian water of Nebraska good water?

Mr. HICKS. Yes; the best I ever saw. The belt runs somewhat west of north. That belt strikes Nebraska. In Knox County there is excellent artesian water to be found and at very moderate expense, but it is not in the belt that needs it. That artesian water is going to be of great value for power, if for nothing else. You can get a great water-power by boring into the earth. In the western region, where irrigation is most needed, the results of exploration for deep artesian waters have so far been negative.

The CHAIRMAN. How deep have they bored in any one place in the western part of the State?

Mr. HICKS. I do not know exactly as to that. No very deep wells have been bored in this region.

The CHAIRMAN. Have any of them kept a record of the conformation in the case of those wells that have been found?

Mr. HICKS. I have no record of wells in this region of greater depth than 500 feet.

The CHAIRMAN. Are there any portions of Nebraska where the water is near enough to the surface to make the use of pumping machinery cheap enough to be practiced to any extent?

Mr. HICKS. I think there are.

The CHAIRMAN. In what portions of the State is the water near the surface?

Mr. HICKS. I might adduce the facts that have come to your own notice as we traveled along this section. The water is standing on the surface in some places as we came along, and I have been informed that here at Ogallalla the water is only three feet from the surface.

Near the headwaters of the Loup River the water lies very near the surface. In many parts there are salt lakes. The water collects in the depressions and makes little salt lakes. In the sand-hills (all things considered the least valuable of all), there are small lakes and the water generally lies near the surface (I do not mean the summit of a sharp peak of a sand-hill), but you can get water and it is remarkable how near the surface you can get it. Wherever there are depressions the water lies very near the surface for wells.

The CHAIRMAN. May not the fact that the water lies near the surface on the Loup and other rivers have something to do with the production of crops there and with extending the belt?

Mr. HICKS. That is an explanation of the productiveness of that region but you would have to go farther to show that the water is there.

The CHAIRMAN. The water is there. It would be increased by additional rain-fall but the water is on the surface. What is the price of coal in this town?

Mr. HICKS. Some gentlemen living in Ogallalla can tell that better than I.

Mr. NEEVES. We do not get it very cheap. We pay $7 a ton for it.

STATEMENT OF ROBERT B. HOWELL, OF OMAHA.

The CHAIRMAN. What is your occupation?

Mr. HOWELL. I practice engineering.

The CHAIRMAN. In what engineering enterprise are you now engaged?

Mr. HOWELL. In hydraulic engineering. We are considering the construction of a canal here in Ogallala.

The CHAIRMAN. From what stream and to cover what land?

Mr. HOWELL. From the South Platte River to cover the land lying between the town of Brewell, about 10 miles above here, and this town.

The CHAIRMAN. How do you expect to get the water out of the Platte?

Mr. HOWELL. By seepage from the sand.

The CHAIRMAN. How are you going to get seepage?

Mr. HOWELL. Either by digging a drainage ditch or by means of galleries.

The **CHAIRMAN**. Explain how you would do it.

Mr. **HOWELL**. The gallery would be a wooden structure made of wood scantling and made in the rectangular form, and placed on the hard pan to form a sort of sewer as it were to carry off the drainage of the sand. This would be laid down and the water led off the pipe. The river falls at the rate of 8 feet to the mile. The pipe would be laid out about 2 feet to the mile.

The **CHAIRMAN** You would go into the sands and sink these galleries to form a body of water, and you would draw that water off by means of pipes and by gravitation with sufficient grade until you got it so that you could turn it into a ditch?

Mr. **HOWELL**. Yes.

The **CHAIRMAN**. Have you prospected the river to find out how much water there is below the surface? What means have you taken to ascertain that?

Mr. **HOWELL**. No means. We have examined and know that the stratum is about 18 feet. By digging anywhere from 6 to 18 inches below the surface the water fills up the cavity.

The **CHAIRMAN**. How wide does the water flow near the surface?

Mr. **HOWELL**. At this point it flows across the whole surface of the river.

The **CHAIRMAN**. About how wide is that?

Mr. **HOWELL**. About 3,000 feet at some places.

The **CHAIRMAN**. Does it also flow beneath the surface in the low bottoms?

Mr. **HOWELL**. Yes. The water seems to be higher in borings that are made below the river bank than in the river itself.

The **CHAIRMAN**. For some distance from the river on either side this water is as wide as the river bed?

Mr. **HOWELL**. Yes, it seems to be a little wider.

The **CHAIRMAN**. How wide at this place is the bottom where you can get the water?

Mr. **HOWELL**. For three-quarters of a mile on each side of the river you could get water for a distance of about 30 miles, I should think, at the highest point.

The **CHAIRMAN**. Is it not best to make a ditch deep in proportion to the width?

Mr. **HOWELL**. Yes, the theoretical form for a ditch is a deep ditch.

The **CHAIRMAN**. The practice in Colorado and this country seems to be to make a shallow ditch. Do you agree with that practice as to the economical preservation of the water?

Mr. **HOWELL**. No; I think a deeper ditch would be the best, but deeper ditches are more expensive, and it is only in cases of high water that they would carry a maximum amount.

The **CHAIRMAN**. How far up the river are you going to take out this ditch?

Mr. **HOWELL**. About 12 miles.

The **CHAIRMAN**. Are you going to continue it a considerable way down.

Mr. **HOWELL**. No, we are going to stop at this point.

The **CHAIRMAN**. There is land below to which it may be carried down if you should wish, is there not?

Mr. **HOWELL**. Yes.

The **CHAIRMAN**. Is it possible to get the water of the South Platte, commencing in Nebraska, onto the table-land?

Mr. **HOWELL**. Yes, that can be done.

The CHAIRMAN. Beginning in Nebraska and extending up and down?

Mr. HOWELL. Yes, I think it can, without doubt.

The CHAIRMAN. Are there any places in the river between here and the mountains where there is rock formation to bring the water to the surface?

Mr. HOWELL. Yes; there is one place that I know of.

The CHAIRNAN. How far up is that?

Mr. HOWELL. Near Fort Morgan.

The CHAIRMAN. How much water runs in the river at that point?

Mr. HOWELL. About 122 cubic feet per second, but the rock is only exposed on one side. Over that rocky place there are 122 cubic feet per second running.

The CHAIRMAN. You do not know what the inclination of the rock is on the other side of the river?

Mr. HOWELL. No.

The CHAIRMAN. Or whether the rock rises again so as to form a dam—that has not been prospected?

Mr. HOWELL. No. In Colorado they are constructing a canal to take the water out, and there is a point above where a dam has been constructed across the river, from bed-rock to the surface, to force the water in the river to the surface.

The CHAIRMAN. It follows the bed-rock?

Mr. HOWELL. Yes.

The CHAIRMAN. How much water does that force to the surface in ordinary times?

Mr. HOWELL. The gentleman who constructed it calculated that it was 100 cubic feet per second that was running through the canal, but there was some being lost at the same time going down the river.

The CHAIRMAN. The dam did not stop it all?

Mr. HOWELL. No. The dam was just up to the surface of the sand

The CHAIRMAN. How far is that from the State line?

Mr. HOWELL. That was at Fort Morgan. I do not know exactly where it is. It is beyond Sterling.

The CHAIRMAN. How long a ditch have they run from that down?

Mr. HOWELL. I think it is about the neighborhood of 64 miles altogether.

The CHAIRMAN. It is getting down pretty well to the State line?

Mr. HOWELL. No. The main or supply ditch follows the contour of the surface and there is a lateral. Altogether, I think, it is 64 miles long.

The CHAIRMAN. On which side of the river is it taken out?

Mr. HOWELL. On the south side.

The CHAIRMAN. Why would it not be a good plan to unite with those people and take out all the water and bring it down as far as it will come?

Mr. HOWELL. Because 122 feet per second would be insufficient.

The CHAIRMAN. But in flood-time there is a good deal more?

Mr. HOWELL. Yes; but they have not practiced much the saving of water in winter.

The CHAIRMAN. Water saved in winter is just as good as that saved at any other time, is it not?

Mr. HOWELL. Yes.

The CHAIRMAN. Suppose you make reservoirs along on the highest points, could you not irrigate a good deal of your land in that way?

Mr. HOWELL. Yes; not only there, but upon the tables. There are many natural reservoirs where water might be stored, and, although it could not be used for irrigating, it could be left there to temper the winds.

The **CHAIRMAN.** But it could be stored and used for irrigation when wanted.

Mr. **HOWELL.** It might. If you could not get the water on the land to irrigate, it would be good to let it stand around in small lakes.

The **CHAIRMAN.** Taking the river out at the point where the rocks appear, what would be the lay of the land, of the topography, from there down?

Mr. **HOWELL.** There is a gradual slope to the river. The slope ends at the table-land above.

The **CHAIRMAN.** How does the land on the South Platte along here by Fort Morgan and Sterling compare with the land on the other side as regards its natural fertility?

Mr. **HOWELL.** The soil seems to be sandy about Fort Morgan.

The **CHAIRMAN.** On which side?

Mr. **HOWELL.** On the south side.

The **CHAIRMAN.** Much more so than on the north side?

Mr. **HOWELL.** Yes.

The **CHAIRMAN.** Is that true all along for a considerable distance that this is really somewhat of a sand-hill region on the south side?

Mr. **HOWELL.** I think it is.

The **CHAIRMAN.** Are there any other views you wish to present?

Mr. **HOWELL.** There is one point which I think is a good one, that is, to make a series of reservoirs or lakes on the table-lands, using the spring water. Although the water can not in many cases be used to irrigate land, at the same time it would be making innumerable lakes which would increase evaporation and dew. Whether it would have any effect on the rain-fall is uncertain.

The **CHAIRMAN.** Can you get reservoirs and use the storm water?

Mr. **HOWELL.** I think the storm water is all held there now. I think there is only one draw that extends up to the table-land between here and Grant, about twenty miles south of this. It does not seem that any great quantity of water ever passes at that draw.

The **CHAIRMAN.** Is there a lake there?

Mr. **HOWELL.** No. There is sort of dry lake but the water is stored in the shallow lakes until about this time. Then evaporation takes the greater portion of it. There are wells there 200 feet deep and the strata there are ordinarily pervious to a great extent.

STATEMENT OF C. H. BROWN, OF KEITH COUNTY.

The **CHAIRMAN.** How far from this town is your county?

Mr. **BROWN.** Seven miles southeast.

The **CHAIRMAN.** What is the character of the county on the other side of the river?

Mr. **BROWN.** It is very level and smooth. It has a fine soil. It is also indented with what are called in this country lagoons. You will find a lagoon on an average to a quarter section and from that more. Those lagoons in extent will run up from 4 acres to 160.

The **CHAIRMAN.** Does much water collect in those during the storms?

Mr. **BROWN.** Some seasons they have been partly filled with water but never full.

The **CHAIRMAN.** Do they discharge the water into the Platte?

Report on Irrigation.

Mr. Brown. But very little.

The CHAIRMAN. They have no outlet?

Mr. BROWN. No.

The CHAIRMAN. There are depressions in the earth.

Mr. BROWN. Yes. There is not water enough falling to overrun these lagoons at any time.

The CHAIRMAN. Can you not build a dam across them and make a pond?

Mr. BROWN. There are already ponds.

The CHAIRMAN. But you say they are so low that you can not get the water to use?

Mr. BROWN. In some places. Some of them are too low, and you can not drain them on to the land, but others on the high points could be used for irrigation. There are several ridges of land that are a little higher than the balance, and those ridges generally have the most lagoons.

The CHAIRMAN. The lagoons are almost too large to make ponds of, are they not? You do not have water enough to fill them?

Mr. BROWN. We never have had them all filled in the six years that I have been here.

The CHAIRMAN. Could you not make ponds or small lakes and fill them?

Mr. BROWN. We could if we had the water.

The CHAIRMAN. Some water comes down I suppose?

Mr. BROWN. Yes.

The CHAIRMAN. How is the lay of the land between the Republican River and the Platte?

Mr. BROWN. There is a natural fall to the south.

The CHAIRMAN. And there are table-lands extending along between the Republican and the Platte, are there?

Mr. BROWN. Yes.

The CHAIRMAN. About what elevation is there above the Platte?

Mr. BROWN. About 200 feet from the water-bed. That is about the depth of our wells—from 150 to 200 feet.

The CHAIRMAN. Is it good land?

Mr. BROWN. The nicest I ever saw.

The CHAIRMAN. Do you raise regular crops there without irrigation?

Mr. BROWN. No.

The CHAIRMAN. Can a farmer prosper there without irrigation?

Mr. BROWN. No.

The CHAIRMAN. It is not a good place for homes, then, without irrigation?

Mr. BROWN. No.

The CHAIRMAN. Have you tried it thoroughly to ascertain?

Mr. BROWN. I have tried it for six years.

The CHAIRMAN. Do you know anybody who knows it any longer than you do?

Mr. BROWN. No. I plowed the first acre of land that was plowed in this country.

The CHAIRMAN. And during the six years' experience you have come to the conclusion that it will not do to try to farm without irrigation?

Mr. BROWN. I have.

The CHAIRMAN. Is that the experience of your neighbors?

Mr. HOWELL. Yes, as far as I know.

The CHAIRMAN. You came here under the expectation that you could do it?

Mr. **BROWN.** Yes.

The **CHAIRMAN.** And you have been disappointed?

Mr. **BROWN.** Yes. Some years we have raised a particularly good crop and some years nothing. This year we have nothing at all as far as corn goes, though we have a middling fair crop of wheat and a partial crop of rye.

STATEMENT OF W. L. GOULD, OF OGALALLA.

The **CHAIRMAN.** How long have you resided here?

Mr. **GOULD.** About three years.

The **CHAIRMAN.** You may state anything that occurs to you in reference to storm-water and other water for irrigation.

Mr. **GOULD.** My experience has been this, that when we have abundance of rain through the winter, enough to soak up the ground well, there is no trouble about certain classes of crops growing; but if we have a dry winter we are apt to have a dry spring following, and not sufficient rains to grow crops. I know this, that in these table lands between the two rivers nature has provided a number of places, if utilized, to fill up with an abundance of water during the winter, which could be utilized during the summer. I have driven extensively over the country.

The **CHAIRMAN.** You think reservoirs would be filled if they were made?

Mr. **GOULD.** Yes.

The **CHAIRMAN.** Have there been any experiments made here to show what reservoirs can do?

Mr. **GOULD.** We have seen farmers who have built dams on small streams and have used that water for irrigation on whatever surface was below, and with good results.

STATEMENT OF FRANCIS M. SMITH, OF OGALALLA.

The **CHAIRMAN.** Where do you reside?

Mr. **SMITH.** In Ogalalla.

The **CHAIRMAN.** Are you a farmer?

Mr. **SMITH.** I have had experience in farming this season.

The **CHAIRMAN.** Have you ever constructed a reservoir here to save water?

Mr. **SMITH.** Yes, we constructed an irrigating ditch, and have been using the water this season, and it has been successful.

The **CHAIRMAN.** Give us some information as to it.

Mr. **SMITH.** We have our farm over on the north side of the North Platte River, about 15 miles northwest of this. There is a small stream called Sand Creek running a couple of miles on our property. My experience is that, in this section of country, farming is unsuccessful. I have never seen a full crop grown yet for the three years that I have been here. We went to work and constructed a dam across this stream and put in a canal for a distance of about 3 miles (myself and my neighbor), and we have been using the water on 40 acres of ground that we broke this spring. We put that to corn, and it is a very heavy piece of corn. We consider it a full crop. My neighbor also uses it on 40 or 50 acres, and he got a good crop. Where the water failed to reach the crop the corn was a failure.

The **CHAIRMAN**. How much water did you store by your dam?

Mr. **SMITH**. I think we have about 1,400 cubic inches.

The **CHAIRMAN**. Per second or what?

Mr. **SMITH**. All the time.

The **CHAIRMAN**. Does the stream furnish that, or did you increase it by your dam?

Mr. **SMITH**. We increased it by the dam. We turned the stream.

The **CHAIRMAN**. Did you make a lake?

Mr. **SMITH**. No, we did not mean to make a lake. We live on the bottom, on the north side of the river, in the valley, and we constructed a dam there and turned the stream simply.

The **CHAIRMAN**. How is that stream in winter?

Mr. **SMITH**. There appears to be just as much water there in winter as in summer.

The **CHAIRMAN**. If you had a reservoir in there, so that you could save that water the year round, you could do a good deal more, could you not?

Mr. **SMITH**. Perhaps so, but we use it as it is to irrigate about 80 acres.

Director **POWELL**. What did you mean by 1,400 inches of water?

Mr. **SMITH**. That would mean 1,400 inches of solid water; what the ditch would carry.

Director **POWELL**. In how much time?

Mr. **SMITH**. It would carry that by the minute or second, just as it would run.

Director **POWELL**. Have you ever mined?

Mr. **SMITH**. No, I never did mine.

Director **POWELL**. You do not know what a miner's inch is?

Mr. **SMITH**. No.

Director **POWELL**. How wide is your ditch?

Mr. **SMITH**. I think it is about 3 feet in the bottom.

Director **POWELL**. And how deep does the water run?

Mr. **SMITH**. I hardly know the depth. We have never measured it, but when we filed our right under the irrigating law there were men who appeared to understand the nature of irrigation that we consulted, and they said that there were about 1,400 cubic inches of water in that stream.

STATEMENT OF J. J. McINTOSH, OF SIDNEY.

The **CHAIRMAN**. Do you require to irrigate your land in order to produce crops?

Mr. **McINTOSH**. We irrigate there as much as we can. Irrigation is not carried on there, however, to any very great extent.

The **CHAIRMAN**. Could you produce crops there without irrigation?

Mr. **McINTOSH**. No, not a full crop.

The **CHAIRMAN**. What efforts have been made to irrigate there, and what are the chances to irrigate?

Mr. **McINTOSH**. The chances are good to irrigate there, as stated by Professor Hicks. There was no attempt to do any farming there until the year 1884. The people that came there to settle came with the understanding that irrigation was not required, and it was not expected at all that people would have to irrigate. They supposed that there was sufficient rain-fall to produce a fair crop after the land was properly tilled. But many settlers came in and many went away, and at no time since then have they succeeded in raising a full crop of anything. That is about the truth of the matter in few words. I have lived in that county on and off since 1870.

The **CHAIRMAN.** They have irrigated some in your county, have they not?

Mr. **McINTOSH.** They have irrigated some along the Lodge Pole.

The **CHAIRMAN.** What have been the results of irrigation there?

Mr. **McINTOSH.** When they have irrigated the results have been very satisfactory.

The **CHAIRMAN.** What are the facilities for irrigation?

Mr. **McINTOSH.** The facilities are good there.

The **CHAIRMAN.** The Lodge Pole furnishes some water, I suppose.

Mr. **McINTOSH.** Yes.

The **CHAIRMAN.** Does it have floods?

Mr. **McINTOSH.** We have heavy rain-falls there. Our rain-falls are more spasmodic than the rain-falls in the center or eastern part of the State.

The **CHAIRMAN.** The water runs to waste then considerably, does it?

Mr. **McINTOSH.** Yes.

The **CHAIRMAN.** If that water was stored in proper places would the Lodge Pole furnish any considerable amount of water for irrigating the land?

Mr. **McINTOSH.** It would furnish enough water to irrigate the valley in which it is. My idea about irrigating the table land between the Lodge Pole and the North Platte River would be to take the water from the North Platte River at some point in Wyoming. Then it can be stored in ravines so as to be used in the valley if necessary.

The **CHAIRMAN.** Are you familiar with the North Platte?

Mr. **McINTOSH.** No.

The **CHAIRMAN.** You do not know how much of an undertaking that would be?

Mr. **McINTOSH.** No; but I have been informed by a practical engineer who went out there about ten days ago, that it is perfectly practicable to take the water out of the North Platte River on to the table land.

The **CHAIRMAN.** If that were done and the flood waters were saved you could irrigate considerably?

Mr. **McINTOSH.** We could irrigate the whole divide.

The **CHAIRMAN.** What are the opportunities on the divide for storing storm water in the ravines?

Mr. **McINTOSH.** There are a number of natural basins on the table-land where water stands the whole season round. I have been all over the table land there.

The **CHAIRMAN.** These natural basins are not always the best places. Sometimes you could save water better by making your own basin in the ravine. They are apt to have underground communication and leak badly. Besides, you would need to make the places deep or the evaporation would be bad. Are there opportunities to make ponds there so as to have water?

Mr. **McINTOSH.** Yes.

The **CHAIRMAN.** How deep is the water under the surface?

Mr. **McINTOSH.** On the table land it varies. It runs from 75 feet to 250.

The **CHAIRMAN.** How deep is it in the Lodge Pole Valley?

Mr. **McINTOSH.** Twenty-three feet in the center of the valley and then as you go back toward the table land the depth is greater.

The **CHAIRMAN.** Is there much of a flow of the underground water in the Lodge Pole at 23 feet?

Mr. **McIntosh.** Yes, the wells are inexhaustible.

The **Chairman.** Something might be done, perhaps, by pumping there?

Mr. **McIntosh.** Yes, I think so.

STATEMENT OF THEODORE MENGES, OF KIMBALL.

The **Chairman.** On what stream do you reside?

Mr. **Menges.** On the Lodge Pole.

The **Chairman.** Has there been any irrigation from the Lodge Pole in your vicinity?

Mr. **Menges.** Yes, to some extent.

The **Chairman.** With what success?

Mr. **Menges.** With the best of success. They have gardened some. They have farmed barley and some oats (60 bushels to the acre). The barley was 35 bushels to the acre. They have got excellent corn and all kinds of vegetables in great abundance.

The **Chairman.** What are the opportunities for irrigating on the Lodge Pole in your neighborhood?

Mr. **Menges.** They are good.

The **Chairman.** How can they be utilized?

Mr. **Menges.** By damming the valley.

The **Chairman.** Does much water flow in the Lodge Pole at any season of the year?

Mr. **Menges.** An average of about 12 cubic feet per second flows on the surface. At Kimball we have been at considerable expense to make surveys to find out how much water we have there, expecting to construct a dam and create a water power. It was estimated by an engineer we had there that we had five times as much water flowing on the surface as flood in the stream itself.

The **Chairman.** Is there any opportunity to get that water to the surface?

Mr. **Menges.** We have made soundings across the valley, a distance of about 400 feet, and we find that the distance to rock bottom varies from 11 to 17 feet. About from 2 to 3 feet beneath the surface of the soil we come into water, and from there all the way down into the rock. To bring that water to the surface is very desirable, and we believe it can be done by putting down a dam of some sort on this rock bottom and building it up.

The **Chairman.** They have not resorted to pumping there at all?

Mr. **Menges.** No. We do not know how it is possible even to get down to that rock-bottom. We have sounded with augers but we need to get down so as to make a larger excavation.

The **Chairman.** Is there any other possible water supply for you except the Lodge Pole?

Mr. **Menges.** That is all, excepting the storm waters. With reference to those storm waters we find these lagoons on the divide, and, as stated by yourself and others, I think they are not the best places for catching these waters. Take the whole of Kimball County and you will find it more or less rolling. We have "draws" there in places varying from 20 to 500 feet. They will sometimes have enough water during these storms to swim a horse across them. I know that passing my house and passing the ranch in which I live there is a place that looks perfectly dry generally. It drains a distance of two miles. We have our heavy freshets in July and August and the water was five and six feet deep towards the end of July and first of August. Take the town of Kimball and for two or three hours after a heavy storm you could row a boat through its streets. Kimball drains a body of land of two or three townships, I should say, and when the heavy floods come it makes the whole town practically a lake.

The **CHAIRMAN.** If that water was stored it would do considerable good.

Mr. **MENGES.** Yes, an immense amount of good.

The **CHAIRMAN.** Would you regard surveys and examinations as to the best points for designation for reservoirs as desirable?

Mr. **MENGES.** Very desirable and exceedingly valuable to the people.

The **CHAIRMAN.** We want to know whether money spent in that way will be useful.

Mr. **MENGES.** Very useful and it will be very highly appreciated. In the town of Kimball we have been attempting to develop a water-power and have been at an expense of $500 or $600, which demonstrates the desire of the people to have better water facilities.

The **CHAIRMAN.** What is the fall of the stream?

Mr. **MENGES.** It is 14.4 feet to the mile.

The **CHAIRMAN.** Then a mile of a channel or cut would bring you to the level of the bottom of it, will it not?

Mr. **MENGES.** Yes.

The **CHAIRMAN.** Then you would not have to build the dam so high?

Mr. **MENGES.** No, although we get power of course in proportion as we raise the dam. We have made an examination 10 miles westward from the town of Kimball, and we find that the average will be 15 feet to the mile. In some places the fall would be greater than at others. We had intended to take out a canal, and went up 10 miles and found it 15 feet to the mile on an average. Then we made accurate measurement for 5 miles and for that distance it was 14.4 feet to the mile.

The **CHAIRMAN.** In a couple of miles you would get to bed-rock?

Mr. **MENGES.** Yes. Immediately west of the town of Kimball you will find the bed-rock and all water flows over the rock itself.

The **CHAIRMAN.** Why would that not be a good point?

Mr. **MENGES.** It would be an excellent point, but it would not be at the place where the town wants it.

The **CHAIRMAN.** Suppose you built your dam there and brought the water through the town by a flume or pipe?

Mr. **MENGES.** That would do. We want it to make a lake near the town, however, and were willing to put in a little extra expense. In that stream we have 12 to 14 cubic feet to the second. It is supposed that we can have about 25 to 30 by putting this dam down to bed-rock, and possibly more than that. One estimate was that we could have about 60 by putting it down to bed-rock.. If we could save the flood water we would have all the water we wanted for the whole valley and a portion for the divide.

The **CHAIRMAN.** You could build a dam and save the water by that means. I should build a dam where the rock is and I should have a pipe at the bottom—an iron pipe—cemented in so that you could draw the water out and irrigate a great deal of the land. You would want to draw water off in the summer, would you not, for irrigating purposes?

Mr. **MENGES.** I think you would not want it all. By taking the North Platte and going 20 or 30 miles into Wyoming, that is a magnificent divide lying between the Lodge Pole and the North Platte. There are 1,500,000 acres that could be utilized and utilized well. There is practically no waste land at all.

The CHAIRMAN. The Platte River is a large river.

Mr. MENGES. Very large.

The CHAIRMAN. A great deal of it runs to waste.

Mr. MENGES. Yes; a great deal of it. In the spring as much as 1½ to 4 feet in depth over a half to three-quarters of a mile was flowing down.

STATEMENT OF J. A. PHILLIPS, OF GRANT.

The CHAIRMAN. Is there any stream of water in your county?

Mr. PHILLIPS. No; the nearest stream of water we have is 20 miles away. I live 20 miles south of this.

The CHAIRMAN. How would you suggest that this section might be redeemed by irrigation?

Mr. PHILLIPS. We would like to have a ditch commence in Colorado, 20 miles from the Nebraska line.

The CHAIRMAN. Is there any place at which you could get the water out?

Mr. PHILLIPS. There is such a fall that it will come along.

The CHAIRMAN. Suppose you went still farther up?

Mr. PHILLIPS. There is a sand region farther up that would make it difficult to get the water through?

The CHAIRMAN. You want to get below the sand?

Mr. PHILLIPS. We will have to do that, we think.

The CHAIRMAN. You can not raise crops in your vicinity without irrigation?

Mr. PHILLIPS. We can not raise corn.

The CHAIRMAN. Can you raise any other kind?

Mr. PHILLIPS. We can raise wheat, rye, and a half a crop of oats.

The CHAIRMAN. How much wheat?

Mr. PHILLIPS. Eight to 18 bushels per acre, but there is more of it at 3 and 5 bushels per acre than there is at 8.

The CHAIRMAN. How deep is it to water where you are?

Mr. PHILLIPS. One hundred and eighty-five feet.

The CHAIRMAN. You have not tried artesian water?

Mr. PHILLIPS. No.

The CHAIRMAN. Is there an abundance of water when you get down 185 feet?

Mr. PHILLIPS. Yes; we can run a wind-mill constantly with a 2-inch pipe and can not exhaust the supply of water at the bottom of the pipe.

The CHAIRMAN. Have you irrigated any land with wind-mills?

Mr. PHILLIPS. Not to any great extent?

The CHAIRMAN. Have you irrigated gardens?

Mr. PHILLIPS. People have irrigated their gardens that way. In the south part of the county there is a kind of surface spring water, and they had some little crops there. In the eastern part of the county it is lower and they have some better crops there. We do not see our way to farming there unless we can see our way to water.

The CHAIRMAN. Is there any way to store storm water there?

Mr. PHILLIPS. Yes; there are natural reservoirs all over there.

The CHAIRMAN. In these large natural depressions the water evaporates. You would have to find smaller ones.

Mr. PHILLIPS. We could get them of any size.

The CHAIRMAN. You have not tried to make ponds?

Mr. PHILLIPS. I have a small pond which is used somewhat for a fish pond.

The **Chairman**. If it would do for fish it would do for irrigation.

Mr. **Phillips**. Certainly. We can pump water into it.

The **Chairman**. You can not fill it from storm water, then.

Mr. **Phillips**. No. Our rains in the spring are heavy. From January to June we have had for three years past plenty of rain and after that time we have had scarcely any rain. If we had reservoirs prepared we would be able to store that early spring water.

The **Chairman**. And irrigation at the critical time would enable you to raise crops?

Mr. **Phillips**. Yes, without any trouble.

The **Chairman**. If that section were surveyed carefully and places for reservoirs located by scientific men of experience would it be useful to you?

Mr. **Phillips**. I think it would. The majority of our farmers now think that the only thing to be done is to store the storm water.

STATEMENT OF JAMES ROBSON, OF JULESBURG, COLO.

The **Chairman**. What is your occupation?

Mr. **Robson**. I am in the banking business there.

The **Chairman**. Has your attention been called to the deficiency of moisture here for the purposes of growth of crops.

Mr. **Robson**. It has.

The **Chairman**. How long have you been here?

Mr. **Robson**. About two and a half years.

The **Chairman**. Have you looked over the country to see what the conditions were by which farming might be improved and moisture obtained?

Mr. **Robson**. Yes.

The **Chairman**. We shall be glad to have any statements you think proper to make in regard to the matter.

Mr. **Robson**. The land I speak of is between the North Platte and the Lodge Pole Creek, and between the one hundred and second and the one hundred and fourth meridians. From the time I have been in this country I have become convinced that to make a success of corn it is necessary to have more moisture. We have for that purpose, in our town, discussed the matter in our board of trade. There was a committee formed to investigate it and see whether there was any possibility of irrigating the region which I have mentioned, from Julesburg west and northwest. The committee engaged the services of an engineer of Denver, named Wilson, to go across this country and see whether there was any possibility of taking the water from the North Platte and bringing it over toward Julesburg and irrigating there. To make my remarks shorter, I will read a short paper that the committee prepared yesterday, after they learned that your committee was to meet here.

The paper is as follows:

> Our object in laying this scheme before the committee is to call your attention to it, and give it prominence and recognition as an undertaking of great importance and value to a large number of people in one of the most fertile regions of western Nebraska. The practicability of ditching from the North Platte River, at a point northwest of Julesburg about 100 miles, across the table-land, has been established by a preliminary survey. The proposed route is from a point on the North Platte River, near Camp Clark, on to the table-land, and in a southeast direction to Julesburg.
>
> In regard to the quality of the section of country to be irrigated, we would say that we believe that no stretch of country approaching this to any degree in scope and richness has been irrigated in the West.

The soil is first-class; no sand or gravel to be found in the entire distance except in the river bottom.

From the point where the projected route strikes the table land to the terminus there is not one acre of inferior land, and no area can be found that will irrigate to better advantage.

A ridge or divide extends almost the entire route, thus allowing the water to be conducted both ways for many miles. The river bluffs are composed of soil and soft rock. The river bottom contains some sand, the same as is found all along either valley of the Plattes. The survey, which was made by Mr. C. A. Wilson, a civil engineer of Denver, found the fall of the North Platte River to be 10 feet to the mile, and the height of the bluffs about 350 feet. The fall of the table-land is about 7 feet to the mile, the general trend being to the southeast from the starting point. The scope to be irrigated is on an average about 25 miles in width; beautiful, level-lying land, with a ridge running along the center, this making it easy to irrigate the whole scope.

The committee believe that this project bids fair to open up the richest part of the West, and make the whole tract embraced within the scope of the ditch a perfect garden, and the people a rich and prosperous community.

That no ditch in the West would be more profitable to its constructors and satisfactory to its operators.

Mr. ROBSON. I would say in regard to the water supply that the North Platte has always afforded an abundance of water, and that the engineer at the time he was there, just about a year ago, said that there was then an abundance of water for the supply of three or four or half a dozen such ditches as would be necessary to irrigate that region, probably, at that time. The inhabitants around the river there have been there for a great number of years; they said they never knew the river to be so low, although it is probably lower now than it has ever been. Still, if the river did not afford enough surplus water running, I think the possibility of obtaining water enough by creating dams in the gravel is very great, and would be successful. All through this whole region of country there is an underlying stratum of water that is practically inexhaustible. That has been demonstrated without any dispute. It is necessary that dams should be built if anything is to be made out of that country in the way of agriculture. I think that by building dams and running down into this gravel-bed a water supply can be obtained. It may be expensive, but the water is there.

The CHAIRMAN. Do you think an investigation by the Government as to the best mode of doing it, and where the water can be obtained and estimates of cost and reservations made for reservoir sites would be valuable to the people here?

Mr. ROBSON. Very valuable, indeed.

STATEMENT OF C. A. WALKER, OF OGALALLA:

The CHAIRMAN. What is your occupation?

Mr. WALKER. I am county surveyor of this county.

The CHAIRMAN. You are familiar, I suppose, with the water supply about here?

Mr. WALKER. Yes.

The CHAIRMAN. Have you made any surveys in reference to irrigation?

Mr. WALKER. Yes.

The CHAIRMAN. You may state, in your own way, what you have done, and give us your views with regard to irrigation.

Mr. WALKER. I made one preliminary survey on the south side of the South Platte River, beginning at the Colorado line and extending it about 23 miles east. From what I have done I should think a water-supply could be easily obtained at that point, and a ditch could be built at very little expense. There are about 30,000 or 40,000 acres of land that could be put under ditch.

The CHAIRMAN. If a ditch were commenced at that point would it get onto the table-lands?

Mr. WALKER. Not so far down as I came. I should think it would take 30 or 35 miles to do that.

The CHAIRMAN. Can you not go up higher to better advantage, and get a ditch on to the table-lands, or are you in the sand belt?

Mr. WALKER. No. I could have gone 30 or 35 miles further up the river, and by that means it would get to the table-land.

The CHAIRMAN. Would not that be a better place?

Mr. WALKER. I think likely it would.

The CHAIRMAN. How would you get the water from the river?

Mr. WALKER. By means of a gallery going down into the gravel bed.

The CHAIRMAN. Is that ditch going to be constructed?

Mr. WALKER. I do not know.

The CHAIRMAN. What chance is there for storing storm-water on the south side of the river?

Mr. WALKER. There are very good chances. On the south side—in fact, on both sides—of each of the rivers, the North and South Plattes, there are lagoons, the lower parts of which could be dammed up, and I think a great deal of storm-water could be saved.

The following papers were received and filed. The committee then adjourned, to meet at Washington, D. C., on the call of the chairman:

STATMENT OF A. D. SCHERMERHORN, ENGINEER NEBRASKA DIVISION OF THE UNION PACIFIC RAILWAY.

The main line of the Union Pacific Railway, from the one hundredth meridian west to Cheyenne, passes through the western part of Nebraska and eastern part of Wyoming. Along this line the water supply of the road is, with two exceptions, derived entirely from wells, which give a supply ample for all uses of the company. The road lies along the South Platte River and Lodge Pole Creek, and the wells are sunk on this line, varying in depth from 12 to 30 feet east of Potter Station, and west of there from 35 to 120 feet deep. In sinking these wells trouble was often had on account of quicksand.

Following is a list of wells along the above line, with depth, quantity, and quality of water, etc.:

Station.	Depth.	Diameter.	Quantity.	Quality.
	Feet.	*Feet.*		
Willow Island	12½	12½	Ample	Fair.
Brady Island	12	12	do	do.
Maxwell	10	12	do	do.
North Platte	70	*	Limited	Good.
O'Fallon's	15	9½	do	do.
Paxton	19	12	Ample	do.
Ogallala	10	12	do	do.
Julesburg	18	12	do	do.
Weir	17	9½	Limited	do.
Lodge Pole	17	9½	do	do.
Sidney	35	12	Ample	do.
Potter	30	9½	do	do.
Bushnell	40	9½	Limited	do.
Pine Bluffs	40	9½	Ample	do.
Egbert	35	9½	do	do.
Hillsdale	60	9	Limited	do.
Atkins	120	12	do	Fair.

* Four 3-inch pipes.

More or less alkali is found in the water of all the above wells. At Big Springs the supply is derived from a spring on the hill, from which a pipe line is laid to the tank, it being a gravity supply. The water is of good quality, but the supply is limited. At Kimball the water is pumped from Lodge Pole Creek, about 1 mile from the road, direct into the tank. The supply is ample and the quality good.

No storage system in use on the road. No record has been kept by this department of the rain-fall in this part of the State. The rain-fall is light, and what there is generally occurs between the months of January and July.

There are no irrigation enterprises in successful operation, though several plans for the same have been talked of.

At Kearney there is a canal running from the Platte River, which furnishes water power, but is not used for irrigation purposes.

STATEMENT OF ABBEN WOODCOCK, GENERAL LAND COMMISSIONER OF THE UNION PACIFIC RAILWAY COMPANY.

The Union Pacific Company has never made any surveys relative to irrigating its lands. Neither has it at any time published maps or reports on the subject of irrigation. We have nothing in print relative to the matter.

The subject of irrigation is a very important one. The solution of the problem, "How can the millions of acres of our arid lands be irrigated?" may well engage the best minds of our country, and especially enlist the attention of Congress.

There is no more beautiful country in the world than that which lies between the Missouri River and the Rockies, "The great divide of our continent." Richer land the sun does not shine on. The west third of this lovely country is mostly unproductive for the want of water. Where water has been applied to its soil vegetation springs up like magic and grows and blooms with all the luxuriance of a flower garden. Its yield of vegetables, the cereals, and of fruits is very prolific, and the quality is of the very best.

In Colorado, the land to yield must be irrigated. This is also true of Wyoming, Idaho, Utah, Arizona, New Mexico, Nevada, and the south of California.

In Colorado, east of the mountains, the rivers and streams are already tapped by irrigating ditches; and in the driest part of the season hardly furnish sufficient water to irrigate the lands that are already under cultivation. The South Platte, in its meandering course through Nebraska, is but a bed of sand, the water having been taken from it in Colorado. The same may be said of other streams that have their source in the Rockies. In the dry season but little water through these channels reaches the Missouri.

It is supposed that if the few floods that swell those streams in summer were gathered into reservoirs, sufficient water would be furnished to irrigate the lands which are now under cultivation. At present this is not the case. But how can water be procured to irrigate the millions of acres in Colorado that are yet uncultivated and can be used only for grazing land?

In the spring-time of the year the melting snows of the mountains come thundering down the rocky defiles of the mountains in cascades, and the rain-storms at times pour in torrents. These swell the creeks and streams to overflowing, but soon are carried away in swiftly-running currents and are lost in the great rivers on their way to the sea. How can the priceless waters of these spring floods be saved to the parched up and thirsty country? By collecting them into numerous and extensive reservoirs throughout the country. These reservoirs must be strongly and scientifically built. Large canals and ditches must be so constructed that the waters in flood time may be carried from the creeks and rivers at a high elevation into these reservoirs. No water of flood-time must be allowed to escape as long as there may be room in the reservoirs.

There would, of course, be a constant loss of water from the reservoirs by seepage into and through the ground. The water that would escape by seepage would again appear to the surface in the form of springs and little rivulets. These would break out in low depressions of the ground, in ravines, and small valleys.

These springs and rivulets would be utilized by the farmer in watering his stock or in irrigating his orchards and garden.

Reservoirs might be made in the creeks and rivers themselves by building good and substantial drains at certain available places along their courses.

Mr. Gilmore, general manager of the Platte Land Company, Denver (who, by the way, has studied this subject for years), says that in Colorado they estimate that a stream of water equal to 1 cubic foot per second of time is sufficient for irrigating 50 acres. It is believed that could the vast amount of water that falls in spring and occasionally at intervals during the year be saved for irrigation, it would be amply sufficient to make the States and Territories above named bloom like a rose agriculturally. The cost of the construction of such reservoirs, canals, and ditches would be so great, that capitalists, as yet, have not dared to undertake the enterprise. Should our General Government lead off in this great enterprise by making the required surveys in the different States and Territories where irrigation is a necessity, and inaugurate that great work, capitalists, and the people generally, would enthusiastically join in and give every aid in their power.

THE LANDS OF THE UNION PACIFIC RAILWAY COMPANY.

Nebraska.—As far west as North Platte, on the Union Division of the Union Pacific Railway, the country is agriculturally rich and most prolific in crops, and for some distance beyond Julesburg crops are raised successfully without irrigation. In the extreme western part of the State "dry farming" (as cultivation without irrigation is called) has not thus far been entirely successful. Good crops, however, at some seasons in the western part have been raised. The settlers have confidence and believe that ere long in the future the rain-fall will be amply sufficient. The amount of rain-fall from year to year has gradually increased. The rain-fall this year has been abundant and the prospects for an abundant crop are splendid. The company has practically sold its lands in Nebraska. It has but few pieces unsold. Irrigation I do not think is needed in any part of Nebraska.

Wyoming.—The company has sold all its land in this Territory as far west as Fort Steele, with the exception of a few sections. The land was sold for grazing purposes, with few exceptions, to men engaged in raising cattle. We have yet a large body of land in the western part of the Territory, at least 2,500,000 acres, lying on either side of Green River. I have no doubt that a great portion of this land lying west of Green River can be made highly productive and capable of sustaining thousands of people by constructing a canal that will tap the river high up towards its source, by means of which at least two-thirds of the company's as well as the Government's lands can be successfully irrigated. I ask that your committee investigate this subject when in Wyoming. There is no question about the richness of the soil; even that upon which the station of Green River is situated, which seems so sterile. When at that station, please look at the little inclosure of a Mr. Johnson, just south of our track. It is as green and beautiful as a Washington City park—the effects of irrigation. Owing to the high altitude of Wyoming, Indian corn can not probably be raised, but other crops will be a success. Eastern Wyoming is very similar to western Nebraska, and but little irrigation will be necessary. I am of the opinion that the North Platte, flowing through the southeast of this Territory, can be made to yield its waters to portions of land in that part of the Territory. The same may be said of Bear River, in the western part of the Territory. The unsold Wyoming land has up to this date been a source of outgo to the company in the shape of fees paid for obtaining patents and the yearly taxes, and has furnished no income. It now seems probable that these payments will have amounted to so much by the time this land is sold as to largely reduce the net revenue of the company from this portion of its grant.

Colorado.—The company has over 2,500,000 acres of land in this State. The greater portion can be used alone for grazing purposes unless irrigated. In the extreme eastern part of the State settlers on quite a large area adjoining Kansas and Nebraska have been trying farming, but with varying success. To insure crops even here irrigation is necessary. I have written more fully of this State in the commencement of this letter.

Idaho.—The company had no land grant in this Territory, but owing to its Oregon Short Line, and Utah and Northern Railway, it has great interest in the Territory. The land is very rich. The Snake River, having its source in our National Park, and meandering through the central and west portion of the Territory, is capable of irrigating millions of acres, and of making the south half of this Territory as productive and rich as any part of our country. The climate is admirable, and when water touches its soil vegetation seems to spring up spontaneously.

Utah.—The company has a little over 400,000 acres of land in Utah. The greater part of this land is situated in the eastern part of the Territory, adjacent to Wyoming, and is very broken and mountainous. At present the greater portion of it is fit only for grazing purposes. The land in Utah, without exception, must be irrigated to produce agriculturally. The surface of the country is broken into high hills and mountains, very rich valleys intervening. Much of the land can never be reached with water, but many valleys can be irrigated by the outlay of capital, and when irrigated will become surpassingly beautiful like that of Salt Lake. As is well known, the climate of this Territory is superb, and in salubrity can not be excelled. A great many of the valleys are well settled, but there is a large body of land in nearly all of these which can not be farmed either because water is scarce, or can not be got upon it from the streams. A system of water supply from Utah for irrigating purposes would unquestionably open up large and fertile areas in many of the very productive valleys in which the Territory abounds, and be the means of adding a large population to a country blessed with an invigorating and healthful climate and a capacity for producing many and varied crops, not the least of which are fruits of the best quality known.

Kansas.—The company has sold a vast amount of land in Kansas, there remaining yet unsold upwards of 700,000 acres. This land is first class, and lies in the western part of the State. Here irrigation is not needed. The maturing crops at this season of the year were never better, and there is every indication of a very abundant harvest. The air is pure and bracing and the climate healthful.

I am well aware that I have not treated this subject in the manner you wish. What you desire is succinct and definite information as to the practicability and feasability of irrigation in these different States and Territories. As I said, this department has never made any surveys or studied the subject relative to irrigating the company's lands. I am therefore unable to treat the subject in the practical manner it should be.

STATEMENT OF AUGUST V. KAUTZ, COLONEL EIGHTH INFANTRY, COMMANDING AT FORT NIOBRARA.

The Niobrara River flows near the northern line of the State almost its entire length from west to east. The current is very rapid and the volume of water may be roughly calculated by assuming an average depth of 2 feet and an average width of 150 feet. It is a remarkably constant stream, subject neither to droughts or floods. In the past two years it has not varied more than 2 feet between the highest and lowest water. A large portion of the country through which the river flows is sandy and subject to drought, and its value would be vastly increased if the land north and south of the river could be irrigated. The highest areas are not more than 200 feet above the stream, but many large areas are not half so high. The fall of the river is so great that it would seem highly probably that much if not all the land in the vicinity of the river could be reclaimed.

The constant character of the river is due to the fact that it is supplied entirely by springs. The country is underlaid by an impervious strata which forces the surface water it has passed through the sand that overlies it to drain into the river through the springs, thus making the water supply constant and unvarying. The river-bed has cut down into this strata about 100 feet in the cicinity of this post. Beyond this fact the thickness of the strata is not known. Its impervious character, however, suggests the great probability that artesian water could be obtained by boring through it. The material of the strata is a white earth, alkaline, and sufficiently firm to present a perpendicular wall along a great portion of the river, but as far as known it can be bored as easily as chalk. The nearest flowing well to this point is at Fort Randall, on the Missouri River, about 125 miles east of this post. Its depth is said to be something over 600 feet. If the fact could be demonstrated that artesian water could be obtained within 1,000 feet of the surface it would be of incalculable value to this portion of the State.

STATEMENT OF J. S. POLAND, LIEUTENANT-COLONEL TWENTY-FIRST INFANTRY, U. S. ARMY, OF FORT SIDNEY.

My experience in this department is not extensive enough for me to make any valuable suggestions, but I wish to remark that while stationed at Fort Bridger it occurred to me that portions of the country near that post could be made fertile by raising water from an unfailing stream, the Black Fork of Green River, into reservoirs at suitable places along its banks, as can be determined by barometric survey, and large portions of the country reclaimed by irrigating ditches. The soil is fertile and needs only proper moisture to produce anything. I am not prepared to confirm the assertion of a prominent geologist that the plains of southwest Wyoming may yet furnish a valuable fertilizing soil for worn-out districts.

STATEMENT OF E. W. STONE, CAPTAIN COMPANY A, TWENTY-FIRST INFANTRY, U. S. ARMY, OF FORT SIDNEY.

My experience in irrigation has been such only as applies to the cultivation of a company garden. For the successful cultivation of a garden, growing of trees, in fact any product of the earth, on the plains, and I might say through the entire West, irrigation to a certain extent is necessary. In the few places that have come under my observation no organized system has been adopted. Generally streams of water have been tapped, and water, without regard to quantity required, allowed to flow over the surface without means being provided for conducting that not required back to the stream, thus allowing great waste which, as the country settles, causes a scarcity, and in many cases trouble.

In many sections irrigation by flooding the surface is common, which, in my opinion, is injurious. When the flow of water is stopped, the heat and dry atmosphere converts the surface into a hard crust, thus preventing the air from penetrating to the roots of the plants, etc., which is essential to a healthy growth. I have met with the best success in irrigation by means of narrow trenches leading from a main ditch, whereby the water is absorbed in the earth around the roots of the plants and the surface left free and opened.

At this post means of irrigation are furnished from Lodge Pole Creek, the water of which is conducted to the post by a military ditch tapping the creek about a mile and a half above the post, by which means 20 acres in vegetables are successfully cultivated; fine grass plats and a luxurious growth of trees are maintained about the garrison. In this section, as settlers increase, additional acreage comes under cultivation, and timber claims planted, the rain-fall sensibly increases ever year, thus decreasing the demands for irrigation.

At the fair of the County Agricultural Society held at Sidney last year many fine specimens of vegetables and small grains, raised without irrigation, were exhibited. Prizes are only offered for such exhibits as are raised without irrigation in this county.

STATEMENT OF H. L. BAILEY, FIRST LIEUTENANT AND REGIMENTAL QUARTERMASTER TWENTY-FIRST INFANTRY, U. S. ARMY, OF FORT SIDNEY.

Observed the system and results of irrigation over wide tracts of dry deserts in Oregon, Washington, Idaho, Utah, and elsewhere. In Utah, lately, capitalists are forming companies to construct and control great ditches or canals, which will give them power to heavily tax thousands of farmers. Such projects are in contemplation, I believe, in this vicinity of Nebraska. The South Platte River throughout this State is destitute of water in summer in consequence of the use of its water in irrigation in Colorado. The taking of the water should be regulated by law. The soil of these deserts I have mentioned is very rich in agricultural ingredients, and needs only water. The North Platte, 70 miles north of this place, could, I doubt not, be made to irrigate many thousands of acres of Wyoming and Nebraska. I have not been over the ground personally, but I think it would be easy to conduct its waters to these little valleys along the Union Pacific Railway. The benefit of such spread of the water would extend beyond mere wetting of the soil, as the effect of the moisture and resulting vegetation would in time so modify the climate as to produce more rain and dew.

REPORT

OF THE

SPECIAL COMMITTEE

OF THE

UNITED STATES SENATE

ON THE

IRRIGATION AND RECLAMATION OF ARID LANDS.

VOL. IV.—STATEMENTS BY DIRECTOR POWELL AND OTHER OFFICERS
OF THE U. S. GEOLOGICAL SURVEY.
CONSULAR REPORTS.
GENERAL REPORT ON IRRIGATION IN UNITED STATES.
MISCELLANEOUS PAPERS.

WASHINGTON:
GOVERNMENT PRINTING OFFICE.
1890.

VOL. IV.

STATEMENTS BY DIRECTOR POWELL AND OTHER OFFICERS OF THE U. S. GEOLOGICAL SURVEY.

REPORTS OF UNITED STATES CONSULS IN COUNTRIES USING IRRIGATION.

MISCELLANEOUS PAPERS ON SUBJECT OF RECLAMATION.

HINTON'S REPORT ON "IRRIGATION IN THE UNITED STATES." RE-EDITED BY ORDER OF THE COMMITTEE.

WASHINGTON DIVISION.

WASHINGTON, D. C., *January* 17, 1890.

The committee met pursuant to the call of the chairman.

Present, Mr. Stewart (chairman), Mr. Plumb, Mr. Casey, Mr. Moody, Mr. Reagan, and Mr. Jones of Arkansas.

STATEMENT OF J. W. POWELL. DIRECTOR OF THE GEOLOGICAL SURVEY.

Director **POWELL**. Mr. Chairman and gentlemen of the committee, since the return of the committee from the West, having ascertained special questions in which the members of the committee were interested, I have devoted almost all my time to the collection of the data which they seemed to require, and to assembling those data in such manner as to present to the committee a body of material that should as far as possible be a repository of facts in relation to arid lands. For this purpose I have not only devoted most of my own time but have employed from five to twenty-five men in the office of the Geological Survey getting together the facts.

I now present before the committe a map of the arid region exhibiting the distribution of the land already irrigated. The committee will see on this map a red line along the eastern border.

The **CHAIRMAN**. How is that map entitled?

Director **POWELL**. It is entitled, "Map showing the irrigated areas of the United States."

Senator **PLUMB**. That corresponds to the line drawn on other public maps, I suppose; for instance, the one at the White House, separating the arid from the subarid regions?

Director **POWELL**. That map at the White House I made some fifteen years ago. I have more complete data now.

Senator **PLUMB**. Do the lines run to the same places?

Director **POWELL**. Not quite.

Senator **CASEY**. Is that line drawn at about the one hundredth meridian?

Director **POWELL**. It is very near to it, but not exactly at the one hundredth meridian. There is a border zone along the eastern side of the line—a doubtful region—the region in which at some times rain falls in quantities sufficient for agriculture and at other times in quantities not sufficient for that purpose. The line itself is drawn conservatively, so as to include only those areas now generally, perhaps universally, recognized as being arid to such an extent as to require irrigation from year to year.

The greatest change I have made since the old maps were constructed is in the western border. We are able to trace out more accurately the lines on the western border where irrigation is necessary. I have also left out the northern portion of the valley of California in which irrigation is not absolutely necessary.

The CHAIRMAN. In the northern Sacramento Valley?

Director POWELL. Yes.

The CHAIRMAN. Irrigation districts are being rapidly organized there.

Director POWELL. Yes, but I have only indicated here the area where irrigation is absolutely necessary. The total area of the regions thus embraced within the two lines is about 1,340,000 square miles. If we include the subhumid zones on either side, where irrigation must be practiced some years to secure crops, the total area will be about one-half of the United States exclusive of Alaska.

A glance at the map will exhibit the districts of country where irrigation is now in progress. From the data we have collected we find that about 8,000,000 acres of land have been irrigated and are under cultivation, and that a little more than 10,000,000 acres of land are under ditch. I have that all plotted on the map, except some few places yet to be completed—little outlying districts where 10, 20, or 30 acres are irrigated by little springs, etc.—a few in Nevada, Idaho, and Oregon, and some in Wyoming. They will very soon be completed.

I here present a table by States, setting this forth:

IRRIGATED AREAS—TOTALS.

States and Territories.	Under ditches constructed or projected.	Irrigated and under ditch.	Percentage irrigated to total area of State.	Authority.
	Acres.	*Acres.*		
Arizona	455,600	175,000	0.2	T. E. Farish.
California	6,000,000	3,000,000	3.0	R. J. Hinton.*
Colorado	....	2,250,000	3.0	Do.*
Idaho	740,000	400,000	0.7	J. C. Straughn.
Montana	....	†348,000	0.3	R. S. Tarr.
Nevada	....	75,000	0.1	R. J. Hinton.*
New Mexico	1,360,000	638,000	0.8	T. B. Mills.
Oregon	191,000	119,000	0.2	W. G. Steel.
Utah	....	802,000	1.5	F. H. Newell.
Wyoming	1,227,819	†500,000	0.8	E. Mead.
Total	....	8,307,000	....	

*Mr. Hinton's estimates are based on various reports and figures, the details of which are not now accessible.

†Including large areas of hay lands in Wyoming, probably 90 per cent. meadow.

The figures above are not comparable among themselves, as they are derived from many sources and made by various persons, each having different purposes and ideas as to what constitutes irrigation.

NOTE.—Mr. Hinton's figures are those of his report on "Irrigation in the United States" made in 1885-'86 and published in 1887 by order of the United States Senate.

ARIZONA.

The estimates for Arizona are based on the report of Mr. T. E. Farish, Commissioner of Immigration, bearing date May 25, 1889. Following is a summary of his figures:

County.	Reclaimable.	Under ditch.	Cultivated	(Newell) estimated under irrigation.
	Acres.	*Acres.*	*Acres.*	*Acres.*
Mohave	....	....	1,000	1,000
Yavapai	....	....	11,680	10,000
Apache	....	....	9,000	9,000
Graham	....	47,000	....	10,000
Gila	....	....	6,600	5,000
Pinal	....	71,600	12,000	10,000
Maricopa	1,250,000	300,000	132,800	100,000
Yuma	....	30,000	5,000	5,000
Pima	300,000	7,000	5,000	5,000
Cochise	100,000	....	20,000	20,000
Total	1,650,000	455.600	203,080	175,000

COLORADO.—PARTIAL STATEMENT.

District.	Under ditch	Irrigated.	District.	Under ditch	Irrigated.
	Acres.	*Acres.*		*Acres.*	*Acres.*
1, State engineer's report, 1888	150,000	39,720	15	2,771	4,544
2, State engineer's report, 1888	....	46,150	16	32,623	12,713
3	....	108,900	20	396,360	100,610
4	....	69,910	21	57,920	45,183
5	....	86,655	22	46,211	33,855
6	....	50,000	41 and 60, Montrose County	....	*5,000
7	98,558	68,905	40, Delta County	....	*2,000
8	....	3,000	42 and 63, Mesa County	....	10,390
9	6,915	3,740	43, Garfield County	....	1,000
14	13,694	7,264	Total	....	699,539

* Assessor.

The above comprises all the figures, official or otherwise, that are at present in this office. It is evident, on inspection, that these estimates are very incomplete, far below the actual irrigated acreage even in the districts given, while many districts are not mentioned.

IDAHO.

[From the report of the governor, 1889.]

Counties.	Approximate area.	Irrigated and in process as reported.	Irrigable as reported.	The irrigable land now irrigated.	Total area reclaimable.
	Sq. miles.	*Acres.*	*Acres.*	*Per cent.*	*Per cent.*
Ada	2,424	60,000	900,000	6.25	62
Alturas *	2,100	14,500	268,000	5.13	21
Bear Lake	†1,300	21,500	40,000	35.5	74
Bingham ‡	12,364	284,750	2,503,500	10.5	35.5
Boisé	3,024	83,500	262,000	24	18
Cassia	5,100	82,000	655,000	11.1	22.5
Custer	4,350	24,000	446,000	5.1	17
Elmore	2,700	10,000	230,000	4.2	14
Lemhi	4,300	10,000	600,000	1.64	22.2
Logan	5,200	50,000	1,250,000	2.6	39
Oneida	2,600	38,800	148,000	20.8	11.2
Owyhee	7,812	21,300	248,500	8	42
Washington	2,900	40,000	500,000	7.4	29
Total	56,174	§740,350	8,051,000	9.2	24

* Much on Lost River and lava bed. † This area includes the lake. ‡ Much of this is "in process."

§ The land actually under ditch at present can not be much over one-half of this amount—evident from the amount of water known to be used in certain counties. Estimated 400,000 acres now under ditch.

MONTANA.

[From assessor's returns.*]

County.	Cultivated.	County.	Cultivated.
	Acres.		*Acres.*
Deer Lodge	49, 875	Fergus	12, 696
Gallatin	47, 330	Cascade	9, 020
Madison	44, 204	Yellowstone	7, 357
Jefferson	37, 000	Park	6, 759
Meagher	32, 300	Silver Bow	4, 461
Lewis and Clarke	25, 968	Dawson	109
Custer	21, 812	Choteau	14, 378
Beaver Head	20, 971		
Missoula	13, 862	Total	348, 102

*As the statements upon which this table is based were made by an assessor, and were to form the basis of taxation, it is probable that they are considerably under-estimated. I think that it is safe to say that in 1888 there were 500,000 acres of land under cultivation, and the amount is probably not much greater the present year. (Report of R. S. Tarr, June 21, 1889.)

It should be noted that this estimate is based on the assessor's returns of all lands under cultivation.

The largest item of this is 209,000 acres of meadow.

Total acreage of crops (nearly all irrigated)	348,000
Total acreage of meadow	209,000
	139,000

This gives 139,000 acres of small grains and vegetables. This latter figure should be taken in comparison with other States and Territories, since in these latter meadow or grazing lands form but a small item.

NEW MEXICO.

[Estimate of land and ditches by T. B. Mills, June 24, 1889.]

County.	Under ditch.	County.	Under ditch.
	Acres.		*Acres.*
Bernalillo	12, 421	Santa Fé	9, 830
Colfax	13[illegible], 400	Sierra	8, 673
Doña Aña	37, 621	San Juan	20, 000
Grant	8, 721	Socorro	73, 464
Lincoln	100, 000	Taos	88, 763
Mora	51, 279	Valencia	26, 429
Rio Arriba	29, 623		
San Miguel	38, 241	Total	638, 455

Projected ditches and ditches under construction will serve in addition, 722,000 acres.

OREGON.

[Report of W. G. Steel, June 27, 1889.]

County.	Irrigated.	Irrigable under ditches.	County.	Irrigated.	Irrigable under ditches.

* Statistics derived from Mormon Church records.

WYOMING.

[From Meade's letter of May 9, 1889.]

Statement.—November 1, 1888, amount of land under ditch, 1,227,819 acres (1,918 square miles). "Probably below the truth."

Actually irrigated (including hay lands), 500,000 acres; (agricultural, 50,000acres).

Duty, 1 section foot to 80 acres.

Director POWELL (continuing). Do the Senators wish to ask any questions in relation to any special districts? I thought I could assemble on a map a large amount of information and save much oral description. I have had this map engraved. The plates on copper are now in the Geological Survey, and, if desired by the committee, the maps which I present can be incorporated in their report, so that the whole matter may be presented in one body. (See map.)

I have also prepared a map entitled "A map showing the wooded area of the arid region," in which I have delineated in two colors all the forest areas of the region, and it is done with some minuteness and care. The dark green represents all the areas the forests of which are valuable for timber for commercial purposes. Those forests are composed of pines, spruces, hemlocks, firs, and sequoias. (See map.)

The area covered by forests in this manner in that region is less than one-tenth of the arid region, that is to say, one-tenth is covered with forests of commercial value. It must be understood that these forests are all at a great elevation. They are all on the mountains or very high plateaus. The forests grow invariably in regions either where agriculture is impossible or where agriculture pays but very poorly. They are in regions where snow accumulates through many months of the winter, and where frosts may be expected in almost any month of the summer. For that reason the regions where merchantable and valuable timber grows, such as I have been speaking of, have not lands that are susceptible of practical agriculture. They will grow some grains, it may be, and some potatoes, some rye, and a few other things, but in the main, agriculture is impossible there, and the crops which can be cultivated are few. The growth would compare with that of Norway and of southern Alaska.

The **CHAIRMAN**. What is the altitude?

Director **POWELL**. It varies. In the north the lower margin is about 5,000 feet, and that margin rises southward to about 7,500 feet, while the upper margin is about 9,000 feet at the north and about 11,000 feet at the south. It is about at that elevation that the timber is found. This timber, in the main, however, is scant. There are some places where the forests are dense. Usually, the pine and fir and sequoia forests are open. The trees are scattered and the forests are interspersed with glades and prairies in such manner that all the timber could grow advantageously on one fourth of the area they now occupy, and still the ground would not be crowded—the trees would be scant.

Not only are those forests interspersed with prairies and with naked glades and "parks," as they are very often called in that country, but the forest area being, in the main, mountainous area, there are many cliffs, crags, and mountain sides of naked rocks which are not covered with timber. So that on the map an amount of forest area appears much larger than it actually is. On this scale it is impossible to exclude these small tracts which are treeless.

In addition to the forests of commercial value, forests composed in the main of piñons or nut-pines, of cedars, and of small oaks are found in California. These trees are valueless for ordinary commercial purposes. That is, they can not be cut into timber; they are too small for that purpose, but they have great value for fire-wood, fencing, and many domestic purposes. These lie much below the pine forests. These piñon and cedar forests are on the low plateaus and on the rocky hills. In addition to those along some of the streams, as on the Upper Missouri, the Yellowstone, and other streams, down on the bottoms are found forests of cottonwood. Of these all that are worth mentioning are delineated on the map.

The area covered with forests of this class, where the trees are valuable only for fire-wood and other domestic purposes, is slightly greater than the other. A little over one-tenth of the area is covered with forests of this character. Some of the lands covered with this description of forest are valuable for agricultural purposes, but not all. Some are high, others are on rocky hills, and in situations where they can not be used for agriculture.

I wish to incorporate the following table showing by States and Territories the area and character of these forests.

Approximate area in square miles of timbered lands in the arid region.

State.	Fire-wood.	Merchantable timber.
	Sq. miles.	*Sq. miles.*
Washington	1,050	1,080
Idaho	8,600	9,800
Montana	6,500	21,000
Oregon	3,500	8,700
Wyoming	7,300	15,700
South Dakota	2,400	400
North Dakota (river bottoms)	200	....
California	20,300	11,000
Nevada	5,400	700
Arizona	26,510	11,700
New Mexico	21,540	14,490
Colorado	15,000	23,500
Utah	14,000	7,700
Total	132,300	125,970 132,300
		258,270
Total area of arid region, square miles		1,335,126

Senator **REAGAN**. Did you extend your information down to the Texas territory?

Director **POWELL**. I have not hitherto done so. I have only a small portion of the information, such as I gathered this summer, but I have been for twenty years gathering these data in the other regions.

I wish now to say a word or two with regard to the preservation of forests.

The forests are destroyed frequently by fire. The amount of timber used by man is comparatively inconsiderable. I witnessed one fire twenty years ago in Colorado which destroyed more timber than the people of Colorado have used since the settlement of that country, and I have myself witnessed five or six fires in Colorado of equal magnitude. I have witnessed elsewhere in the mountains very great fires. They are well known. As some of you will remember, during the journey of the committee this past season we passed through the mountainous region of Montana, eastern Washington, eastern Oregon, Idaho, and down into Utah before a mountain was seen, because the whole country was enveloped in smoke as in a dense fog.

These fires are exceedingly destructive. I have with me a map of Utah which will show how destructive they are. This map was made twelve or fifteen years ago and shows simply the areas which were destroyed by fire at that time. I will present it to you for a moment so that you may see how it looks. (See map.)

The blue represents the standing timber at that time—twelve years ago. The brown represents the burned timber at that time. I have no doubt that if a map were made to-day of that same region it would show that much of that blue area has been destroyed in twelve years. The green exhibits the irrigable areas as determined at that time. The forests are chiefly coniferous and needle-bearing, and are charged highly with resin, and so exceedingly inflammable; and for this reason fires are greatly destructive. Then, since the white man has come into the country, the forests have not been annually burned. In old times, when the Indians occupied that country, they systematically burned the forests every fall. By so doing they unconsciously, though not for that purpose perhaps, prevented the total destruction of those forests.

If a forest of coniferous trees is protected from fire for a series of years until the ground is covered with an accumulation of cones, needles, twigs, and brush, then the fires have something on which they may feed. If then, by accident or design, a fire is kindled in such a forest it sweeps through and destroys it. So the forests are being destroyed not for want of protection, but because they are protected from fires. The only proper preservation of those forests consists in a systematic annual burning. If this burning is accomplished at a season of the year when the ground is not too dry the whole accumulation on the surface of the ground may be burned up and destroyed and the trees remain.

Senator **JONES**. Do you think it would now be practicable (with the accumulation of underbrush that years have produced) to burn any of those forests without destroying the timber?

Director **POWELL**. Yes; if burned in seasons of dampness, when the forests are not too dry. Fires are destructive in seasons of great dryness or aridity.

Senator **JONES**. Then, in the districts where the forests have been destroyed by fire, the annual burnings would have to be dispensed with until the young trees got sufficiently large to be safe from destruction by fire?

Director POWELL. If the burning were done at a dry time the smaller trees would be burned; but if the fires were set at a comparatively wet and moist time, and systematically, and if small areas were burned, and burned out, and started again when not too dry, they could be burned without destroying the small trees. In this matter I have had some experience, for I was a farmer's boy in a prairie region and have taken part in such matters. I have burned forests for their protection many times in my life.

The arid region, as I have shown, has already been developed to a great extent for agricultural purposes. In that region there are mines of gold, silver, lead, iron, coal, and so forth, so that a great deal of the country is being settled and in some places it is comparatively densely settled, so that population is now distributed in every valley of importance throughout the region.

In the progress of irrigation and development of that country by which 10,000,000 acres of land have been put under canals, and provision made for the irrigation of that quantity, a large experience has accrued, so that the problems involved—scientific, industrial, and political—have been pretty well developed.

I now show you a map of the arid region exhibiting the areas underlaid by coal, so far as the coal of that country has been determined.

You will observe that in the northeast there is a very great area, in the Dakotas and Montana, but that these areas decrease elsewhere in size, and that in Nevada and the western part of the arid region the coal areas, so far as they are known, are small. You will see them scattered about in various places on the map. (See map.)

This coal is all of a comparatively late age; that is, it is of a late age as compared with the coal of the eastern part of the United States. The coal of the East is of the Carboniferous age. The coal of the West is of the Cretaceous and Tertiary ages, but it varies in character very much. It varies from a brown, soft, friable lignite, found in many places, to the most valuable, dense, hard, anthracite.

Senator CASEY. Where are the anthracite fields?

Director POWELL. In Colorado, Arizona, and New Mexico, so far as I yet know. They may be elsewhere, but we do not know of them elsewhere at present.

All these coals are valuable for domestic purposes. They are all valuable for the creation of power by steam. A large part of them are valuable for metallurgical purposes. In this connection it must be understood that all coals, wherever found, present in each case a distinct problem for their utilization. When a new coal-field is discovered it is never known to what extent it may be used for metallurgical processes until experiments are made and a new method of coking is devised. A new method has to be invented for every new coal-field. A slight variation in the constant part, such as the bituminous or other quality, compels a change in the processes, and when a new region is discovered it is not known whether it is valuable for metallurgical purposes or not. This knowledge has been gathered now in the arid region. Ten years ago it was supposed there was only one field of coking coal in the West. One after another, however, the fields have been brought in as new methods were invented. I have no doubt that ultimately, as new methods are discovered by chemists and others, the fields of coal will one after another be brought in. In addition to that the fields of anthracite coal are being multiplied by discovery from year to year.

Senator CASEY. The gray lignites may be coked to advantage, may they not?

Director **Powell**. Many of them may be. We have not discovered that all can be; but probably experience will prove that processes will be discovered for the coking of all gray lignites. It is doubtful about the brown lignites, however.

These coal-fields are very rich. They usually have from two to twenty and in some places even fifty beds of coal in one field. These vary in thickness from a few inches to 20, 30, 40, 50, and even 100 feet in some places. So that the coals are, for all practical purposes for our present civilization, inexhaustible.

These areas are such as, it is found by geological examination, are coal-bearing; but they do not always have the coal lying near the surface. In Dakota and Montana part of this coal-field is near the surface and part of it is deeper down at a depth of 2,000, 3,000, 4,000, or 5,000 feet, so that under present conditions not all of that coal area is available. The expense of getting at the deep coal is too great under present conditions in this country. But, notwithstanding all this, there is enough coal shown to exist near the surface in the hills, foot-hills, and mountains to give an ample supply for this country for many centuries.

The **Chairman**. They have some coal supply in the new State of Washington, west of the arid region, have they not?

Director **Powell**. Yes, but you will notice that in these maps I have nothing to do with the humid region at all. There is a very valuable lot of coal in this space that I now indicate [indicating]. The red spots over the blue indicate the more important places where coal is mined; I could not get them all on this map.

Senator **Reagan**. There are coal-fields in the Indian Territory and in northern Texas which are not shown on that map; but that is explained, I presume, by the fact that that region is outside of the line.

Director **Powell**. Yes.

Senator **Moody**. Have you had your attention called to the recent developments of those coal-fields lying west of what is known as the Black Hills?

Director **Powell**. Yes; we are annually collecting the statistics of the coal mines. We have a corps of men engaged on that work.

Senator **Moody**. Are you acquainted with the bed of coal that the Burlington and Missouri River Railroad people have been developing recently?

Director **Powell**. Not from personal observation. I know it only by description.

Senator **Moody**. Have any of your force examined it?

Director **Powell**. Yes; they have analyzed it.

Senator **Moody**. Is that what you call an upper bed, or is it a lower bed?

Director **Powell**. The terms "upper bed" and "lower bed," as used by miners, have no special significance. The coal is Lower Cretaceous coal, but beds are tilted and brought up to the surface in various ways. In one district beds which are geologically low will lie high in the mountains, and beds a few miles away which are geologically high will appear in valleys, because the dipping of the rocks has so placed it.

Senator **Moody**. You are aware, I suppose, that there is a very great difference between those strata of coal?

Director **Powell**. Very great; but the difference does not in the least depend upon the geological horizon of the coal. The coals at Rock Springs, in Wyoming, belong high in the Cretaceous age and are very fine coals. The coals of the Sulphur Creek, 25 or 30 miles away, belong 5,000 feet lower in the geological series, and are not quite so good. In other districts it will be *vice versa*, varying in character, and that variation is owing to the manner in which the coal beds are accumulated in basins.

Senator REAGAN. What are the brown spots indicated on the map?

Director POWELL. Those brown spots indicate the regions where coal is mined in large quantities for commercial purposes. I could not put all of them on the map. They are multifarious, but I put the most important mines in by dots on the map. (See map.)

Senator CASEY. Are there not extensive mining operations in Montana farther north than your map indicates?

Director POWELL. Perhaps there are, but the facts come to my office only once a year.

The CHAIRMAN. These coal areas may be found, on further development, to be larger than are indicated on the map?

Director POWELL. Yes. These that I show are the coal areas as they are known.

The map which I now place before you represents the drainage basins of the arid regions, and indicates to the committee the more important problems which have arisen in each one of these drainage basins represented on the map. For this purpose I will commence with the Arkansas basin, that is, I will set forth some of the more important problems that have arisen in the utilization of the Arkansas and its tributaries. (See map.)

This [indicating] is the basin as outlined on the map. The Arkansas River heads in the great mountains of central Colorado, in regions of perpetual snow, and flows down through the mountains until it debouches into the plains and runs through a great valley across the State of Colorado into Kansas and across a corner of Kansas down into the State of Arkansas.

The mountain region above is cold and inhospitable by reason of its great altitude. Great bodies of snow accumulate there during the winter and frosts may occur during any month of the summer. When it leaves the mountains and strikes the plains a warmer and more beautiful region is reached. In this upper region there are many beautiful valleys, valuable especially for pasturing purposes, and the mountains and hills on either side are covered with valuable forests. But when it reaches the plains it has a broad open valley for its course, and it is below where the waters are chiefly used for irrigation.

During the season of irrigation and in years of scarcity of water and small accumulation of snow, the entire volume of the Arkansas is now utilized. Any increase of irrigation on the Arkansas River hereafter must arise from the storage of the waters which now run to waste from nine to ten months of the year. The great body of the irrigable lands under canal ——

The CHAIRMAN. Let me interpose at this point just one question. Does not a large portion of the water run under ground in the sand?

Director POWELL. Yes. I will come to that point in a moment, if the Senator please.

Senator PLUMB. Speaking of the storage of water there, what is the actual average evaporation in that area each year?

Director POWELL. From standing bodies of water it will vary from 56 to 82 inches per annum, depending upon exposure to winds and upon altitude.

Senator PLUMB. What is the difference between the altitudes in that matter? Is there a greater evaporation in the lower altitudes?

Director POWELL. The higher the altitude the less the evaporation;

the greater the exposure to wind the greater the evaporation, and so on.

The Arkansas has irrigable lands, then, in the mountain region, but they are valuable chiefly for grasses. Below, on the Arkansas and on its tributaries—and what I say in relation to the Arkansas itself is practically true of most of its tributaries—the lands are situated somewhat lower than the land now irrigated in the State of Colorado from this river and its tributaries.

There is a very important and interesting condition which must be explained at this point, for it is a governing condition in the utilization of the waters of most of the rivers of the West. I wish to set it forth somewhat in full that it may be clearly understood. The waters of the West usually head in the mountains. The mountain streams are clear and deep, and in the main run in cañons. When the streams leave the mountains, and reach the plains or valleys below, their character is suddenly changed. The dry plains on either side are covered with dust, and the winds and storm waters blow and wash this dust into the stream. Thereupon, the river or creek immediately changes its character. While above, it was clear and deep and swift, below it becomes broad, shallow, and muddy. You are all familiar with the Platte River and know what the waters of that river are. It is a thin sheet of tawny mud, rolling down to the Missouri. Sometimes it is only 10 to 20 inches in depth, varying in places as you cross it. Nearly all the rivers of that country thus change their character when they leave the mountains, but there are important exceptions.

The point where this transformation occurs in the character of the streams is a critical and important point in the utilization of these waters. If the waters are taken out above this point they are used on land of less value by reason of climatic conditions, as already explained. If they are taken out below this point they are charged with silt and mud, and under these conditions they rapidly silt the ground and injure the lands on which they are placed, and they are especially bad in destroying the irrigation works. Water can not be taken out below this point because in some places the reservoirs will be filled up and the canals choked, and in other places they will be eroded and cut so that they are practically destroyed by the presence of the silt.

Senator CASEY. That is a matter of practical experience?

Director POWELL. Yes. So that it is always highly advantageous to take the water out of the stream at this critical point.

But, more than that; when the waters come down to this point they spread in valleys, like the Arkansas, 1, 2, 3, 4, 5, or 10 miles in width. A low sandy valley is found with a wide channel running through it; a low sandy "bench" on either side. Out into the sands on either side the water runs for miles and is rapidly evaporated, so that in a dry season no waters are used in irrigation. A large stream may come from the mountains of Colorado which may be lost before it reaches the Colorado-Kansas line, and no water whatever pass beyond that line.

In general there is a vast waste of the water in these sands. Only a part, however, of this water in the sands is evaporated; the other part remains in the sands. These sands can be tapped by wells and other methods and the water brought out on the surface, so that it is not all lost in this manner, although the larger part is lost by evaporation.

In the valley of the Arkansas irrigation commenced in the State of Colorado. The people of that region are anxious to increase the area of irrigation, and settlers are going into the upper creeks and into the mountains and upper valleys, and are taking out the water in those upper valleys, to be used in the irrigation, in part, of hay-fields, and are raising some few other crops that may be grown in that cold climate.

Senator CASEY. Some wheat included?

Director POWELL. Not much wheat; the climate is almost too cold for that. There are some valleys where wheat may be grown, but not very many. The use of water in these upper regions is a great waste of the water, because of the climatic conditions, as I have explained. But a man may go on a stream above, and another farther up, and cut off the water from where it is used in the region below. It is a difficult matter, under the present laws of Colorado, to correct that condition of affairs, because it is difficult for the farmer in one county to enjoin by law the farmer above him in another county from using the water. How is he to say to the court that the water which the man above has taken is part of the water which he, below, should get for the use of his farm? Both are using the water that flows in the same stream. To identify the water used on a farm below is a very difficult matter. So that, at present, the tendency is to settle the mountain valleys, and thus to drive the agriculture of Colorado into the mountains, and away from the sunny valleys below. That tendency has only begun in Colorado; but elsewhere the evil is of great magnitude, and is accounted a matter of exceedingly great importance, and will, within the next five or ten years, become a matter of still greater importance to Colorado. The result is the driving of the people into the snowy mountains to live, instead of permitting them to live in the sunny plains below.

These problems that I have mentioned are inter-county, inter-community, and inter-farm problems. A new set of problems arises from the fact that the Arkansas passes the Colorado line into Kansas, and in Kansas the people have to resort to some extent to irrigation. In the past year they have developed some irrigation in that region. The water which they use flows from mountains far away; and the people of Kansas desire that the water shall be allowed to flow in its natural channel until it reaches their State, while the people of Colorado insist that they themselves have a right to the water in their State. This brings up an inter-state problem which has come to be a serious one.

Works have been constructed in Colorado, near the line of Kansas, and across the line in the State of Kansas, to irrigate lands to the amount of over 100,000 acres, and works are projected to be constructed this season, and are in part now constructed, to irrigate four or five times that amount. Should there be one, two, or three wet seasons on the upper Arkansas, and the present season is one of great snow-fall up to the present time, the river will supply water to those lands, but only on condition that it is not used above in Colorado. In this State, however, they are constructing works on a very much larger scale, and if these works are finished the waters of even a season of great precipitation will be used in Colorado, and no supply will be afforded to Kansas, except such waters as are taken from the sands of the valley.

Passing from the Arkansas to the Pecos we find problems of the same character. The Pecos rises in New Mexico and flows through a portion of Texas until it reaches the Rio Grande. This is the drainage basin of the Pecos, as shown on the map. The waters of the Pecos are now, and have for years been, used in New Mexico, in part, and to some extent in Texas. Within the last eighteen months or two years the development of irrigation on the Pecos, in New Mexico, has very greatly increased. There has been some increase of irrigation development in Texas, as the maps I have presented will show. There are companies at work this winter, with sufficient capital, engaged in the construction of canals in

New Mexico, and of dams, and to some extent of reservoirs, which, when completed, will take the waters of the Pecos, in New Mexico, and cut off the entire supply from Texas, and as the matter now stands all irrigation, ancient and modern, on the Pecos, will be swept out of existence in two years, unless some supply is provided other than that of the Pecos during the season of irrigation. It is, therefore, an inter-state problem. (See map.)

I will proceed to explain some of the problems which have arisen on the Rio Grande. For two or three centuries the Spanish people who settled on the Rio Grande have been irrigating the soil of that valley, and there are many Spanish or Mexican settlements scattered along its course. The Rio Grande heads in Colorado. It passes into New Mexico and runs southward across that State until ultimately it becomes the boundary line between Texas and the Republic of Mexico. It is in New Mexico, in Texas, and in old Mexico that this ancient irrigation is found. In modern times, or within the last five years, the waters of the Rio Grande have been taken out, and are now being taken out, in Colorado.

I am informed by the engineer of that region, who has just come here, and who has general charge of those works, that it is proposed, before the end of another season, to have canals and works ready for the irrigation of 1,500,000 acres, and that already works are prepared for the irrigation of more than 1,000,000 acres. The irrigation of that region and the waters of that region, in the main, are under the control of an insurance company, which goes into that region, takes out the water, establishes rights to the waters of the country, and sells those rights to the people and in part buys up the land, so that the company owns not only the water and distributes it to the people, but it in part owns also the land.

Passing into New Mexico, then, the water that practically heads in the high mountains of Colorado is largely, almost wholly, cut off from the Rio Grande, so that no portion of the water that heads in these mountains where there is a great precipitation will cross the line into New Mexico. Already the effect of that is seen in Mexico along the lower Rio Grande. During the past season the Rio Grande was dry for many miles below El Paso, which is situated near the line of New Mexico, Texas, and the Republic of Mexico. The Rio Grande was dry there, and dry for 360 miles above that point; so that the people of the lower valley of the Rio Grande in New Mexico, and the people of Texas below, and the people of the Republic of Mexico, had no water. The sand was blowing across the channel of the river, and instead of the space being covered by waves of water it was, when I saw it last, filled with sand dunes.

Senator PLUMB. Was not that due more to the absence of snow in the upper mountains at the head of the stream than to the taking out of the water from the upper stream?

Director POWELL. It is a complex problem. It is due in part to that.

Senator PLUMB. Has there not been a lack of snow during the last year, compared with former years?

Director POWELL. There has not been as much snow as usual.

Senator JONES. Is the Gila a tributary of the Colorado?

Director POWELL. It is a tributary of the Colorado.

The taking out of the water in Colorado subtracts from the river the volume of water which might come from those mountains. In a wet season there is water enough for all, as irrigation is developed to-day, alike in Colorado, New Mexico, Texas, and the Republic of Mexico. But in a dry season the supply is entirely insufficient for all the lands now under canals. If in such seasons the water is used in Colorado and in upper New Mexico it is entirely cut off from lower New Mexico and from the valley of the Rio Grande immediately below El Paso. In a dry season nothing can be raised in the lower region, and sometimes dry seasons come two or three together. One dry season when lands are dependent upon irrigation is disastrous, because fruit trees, vineyards, and all perennial plants are killed. One or two such destructive seasons drives all the people away from the country.

Senator PLUMB. Is any part of that water returned to the river by seepage?

Director POWELL. Yes.

Senator PLUMB. What proportion do you know?

Director POWELL. About 50 per cent.

Senator PLUMB. About 50 per cent. taken from the canal would be returned to the river in the seepage?

Director POWELL. Yes, in careless irrigation. In careful irrigation, like that practiced in southern California, a much smaller amount is returned. With the best irrigation, none is returned.

Senator REAGAN. I put questions to some witnesses with regard to that return of water. It was stated that no provision of law had been made to compel persons taking the water for irrigation to return it to the river.

Senator PLUMB. The question I asked Major Powell was on a somewhat different line. I referred to the return of water by seepage, what would be returned to the river by soaking through the ground into the subterranean channels and be then returned to the river.

The CHAIRMAN. That water does not return or reach the river for the first year or two.

Director POWELL. Being asked by a committee of the Senate to investigate that subject I have for the last eighteen months been investigating it, and I have some facts to set before you in their order when I come to them.

Irrigation has also been greatly developed in New Mexico. The tributaries of the Rio Grande are being taken out in many places. Many streams are being taken out and the water spread upon the land. The Rio Grande is a clear stream until it passes Embudo Cañon, in northern New Mexico. From the mouth of the Chama downward it is a river of mud like the Platte, the Chama being also a river of mud.

Senator CASEY. Will you indicate on the map just about where that occurs?

Director POWELL. There [indicating on the map] is Embudo Cañon. It is a clear stream above that point; it is a river of mud below that. It is suddenly transformed, like the Platte, the Arkansas, and many other streams in the West. (See map).

Senator CASEY. That is after it has left the mountains?

Director POWELL. Below where it leaves the Embudo Cañon and receives the Chama. The water of the upper valley is being used to such an extent that the water of the lower valleys is being taken away from those who have been using it.

As long as no water is being stored in lakes, natural or artificial, or in reservoirs, irrigation in any district depends upon the flow of water through the season of irrigation. That season varies in different portions of the United States from a little less than two months to a little more than three months. Perhaps on the Lower Colorado it will be five months, but in general it varies from two to three months. The irrigation practiced in this manner has a practical limit placed upon it by the dry season. For if in seasons of greater humidity larger areas are brought under ditches, when seasons of greater dryness or aridity come the farmers depending on such waters are destroyed. The trees and vines that are growing become dried up and the seeds go to waste and the canals are filled with sand by the winds. The limit of agriculture is set by the dry season. Hence it may happen, and will happen on the Rio Grande and elsewhere, that in seasons of great humidity there will be sufficient water flowing during the season of irrigation to supply the wants of all the people now engaged in irrigation there and of the people who will want water under the works projected during the past year. But during the season of drought the amount of water is insufficient to serve the land already provided with canals.

A part of the waters that are spread upon the land are returned to the rivers, as shown by the investigations that your committee have been making this year. We have in Colorado and elsewhere studied certain streams that were all taken out and spread upon the land. We have measured the waters thus spread upon the land while being spread. We have then gone below, where these waters have been recovered—where the waters flowing from the irrigated land have been used again—and we have measured the waters thus used again, and have found that the conditions for the recovery of the water vary greatly; that they vary greatly for very important reasons; that in extreme cases 70 per cent. of the water returns to channels immediately below the place where it is used, and 30 per cent. only is evaporated. But that is under conditions where an excessive amount is put on the lands by the farmers.

Growing plants evaporate three hundred times their own weight of growth annually. Whatever the crop may be, whether corn, grass, or wheat, that grows in one year, it will evaporate into the heavens three hundred times its own weight of water. If, then, a crop is raised on a field which is irrigated, and a farmer is careless to such an extent that the field is covered not only with the corn or other crop he desires to raise, but also with a dense growth of weeds, the evaporation from that surface will be enormous. But if his field of corn is well cultivated, and if speedily after each irrigation he turns, with a harrow or raking tool, the ground between the rows, so as to have the ground mulched with a thin surface of soil, the evaporation is at a minimum. The great duty of water which they have secured in Southern California is secured by perfect cultivation, but when the cultivation is bad it requires two or three times the amount of water that is required when the cultivation is good.

There are some other conditions affecting the return of the water besides the two mentioned. Something in the nature of the soil and something in the condition of the slopes determine how much of this water can be recovered, but under the most favorable conditions we find that about 70 per cent. can be recovered to be used again. Under some conditions, however, only 30 per cent. can be recovered. That depends in part on the condition of the slope, in part on the subsoil itself, and in part on the condition of the soil, as well as on the conditions of the channels below in which it may be gathered. Under the best conditions and with thorough cultivation nothing is returned.

The CHAIRMAN. Is there not another condition—the condition of time when getting the ground saturated in the first instance?

Director POWELL. Yes.

The **Chairman**. We had an illustration of that at Fresno and other places.

Director **Powell**. Yes; and it is universal. It will be noticed all over the country, where it is properly studied. A very large amount of water is necessary to saturate the soil the first year. The maximum duty of water is not reached until two, three, four, or five years of cultivation have been had. So that the claims which the people set up to the amount of land which can ultimately be redeemed by the irrigating works already constructed are well maintained by the fact, because although to-day the water may be used to the utmost extent, next year larger areas can be irrigated, and the year after still larger areas, and this for a term of years will increase until after a few years the whole duty of water can be secured. When the whole duty of water is secured, the land well cultivated and economically irrigated, but little will return to the streams.

In the valley of the Rio Grande the greater portion of the water during the season of irrigation is lost in the sands, as in the valley of the Arkansas. If the water of the Rio Grande is compelled to flow across the line from Colorado into New Mexico, it will destroy from 1,000,000 to 1,500,000 acres of agriculture above, in order to save 200,000 or 300,000 acres in the valley below. The water can not be used below for the benefit of the greatest number of people. It is important that irrigation in Colorado which is already established and in progress of establishment should proceed.

But what remedy have the people below to save their property from destruction? The lateral streams which come in are being taken out above in the same manner. Some provision ought to be made by which the waters of these lateral streams, and the waters which flow into the Rio Grande below the Colorado line, should be made first to serve the irrigation already established. As the matter now goes on the new irrigation is destroying the old. When we come down to El Paso we find mountains in that neighborhood the waters of which are competent to serve all the lands on the Texas side and on the Mexican side if they can be utilized—if they can be stored. The waters which can be stored in that region are ample for that purpose, but all the storm waters of the immediate region must be stored.

The **Chairman**. You would add to that the flood waters that come down every winter?

Director **Powell**. I am supposing that there will be no flood waters in dry seasons when the water is properly used above. The people will become better skilled in using the water and there will not be so much waste of the flood waters.

The **Chairman**. Do you think it would be a possibility to use all the flood waters?

Director **Powell**, I think ultimately it would be possible to use all the flood waters. I think the waters which flow from the mountains of New Mexico are ample to supply the irrigation already established and much more.

Senator **Plumb**. What is the valley area of the Rio Grande above this cañon which was spoken of a while ago?

Director **Powell**. The Embudo Cañon?

Senator **Plumb**. Yes; give us a rough calculation as to that.

Director **Powell**. Roughly speaking it would be 5,000,000 acres above Embudo Cañon, good and bad. It is estimated by an engineer of skill and ability that about 1,500,000 acres can be redeemed by irrigation there.

Senator CASEY. The conditions are such as you spoke of a while ago—the land not being adaptable, you think, to cereals.

Director POWELL. Oats and wheat can be raised there but not corn. It happens to be just in the border region between the upper and the lower climates.

Senator PLUMB. Then your opinion is that all the waters that originate either by creeks or otherwise and all the storm waters of that area will be used within the area when this maximum of irrigation is reached.

Director POWELL. That is my judgment.

Senator PLUMB. And then that there will be no water to be utilized in the lower Rio Grande.

Director POWELL. None from this source.

Senator CASEY. Especially if they raise wheat.

Senator PLUMB. They can raise fine potatoes in that country too.

Senator CASEY. There is not the same salability for potatoes.

Director POWELL. Serious troubles are arising in the Rio Grande Valley now and the valley is all aflame. The people are petitioning the Secretary of the Interior and the Secretary of War for troops to protect the old rights from invasion by those who are developing new systems in that country. The difficulty is that at present there is no way by which any court or authoritative officer can say whether a canal shall or shall not be constructed. There is at present no determination of specific waters to specific lands and the area which it is possible to irrigate is six or twelve times as great as the waters will ever serve. What is needed is something by which somebody may be able to say that the waters shall be used on particular lands, so that the valley shall not be left open for anybody to construct a ditch above that of his neighbor and take away from him the water that he has been using. That is the same problem that has arisen on the Pecos.

The CHAIRMAN. What would be your suggestion as to saving the lower waters for the benefit of those people in the Republic of Mexico and in Texas?

Director POWELL. I think a reservoir can be constructed at El Paso. I have had a reservoir planned, and have had the surveys begun in that region, so as to discover the areas that would drain into it, the amount of water in the catchment area, and the amount that would accumulate in the immediate region if it were all cut off above. I find already that there is a large flow into the river in the immediate neighborhood sufficient to fill a great reservoir there which, I believe, would support all the irrigation which has been already developed along the lower river. The catchment area is not fully surveyed; its extent and the character of its slopes are not fully determined; and I can not yet say how much water can be caught.

The CHAIRMAN. Would it be enough for an addition of some new land on the Texas side?

Director POWELL. I believe it would.

The CHAIRMAN. You have stated that it was difficult to have reservoirs on the lower levels. How would you free that reservoir from silt? Would that be practicable? Have you considered that question?

Director POWELL. Yes, I have considered that question with great care. That seemed to be a serious problem. If the reservior is to depend on the bed of the river it is one problem; if on the mountains adjacent it is another problem. If it is to take all the silt of the river, and the waters are not cut off by irrigation above, it will fill in about one hundred years if the flow of the river should be continued for the future as it has been in the past. We have measured the silt of the river from day to day for some months so as to determine that question. There is another source of débris in the hills and mountains that stand about the reservoir sites, the amount of which is yet undetermined, and can not be until the topographic survey is completed.

The CHAIRMAN. Has any method been discovered or devised whereby to free the reservoirs from silt?

Director POWELL. Yes; but nothing that is not somewhat problematical as yet. If filled by the brooks and creeks that flow from the adjacent mountains it can be constructed with dikes or wings on either side so that every stream can be checked on the bench above before it is turned into the reservoir and its flow turned around a long course, and it may be thus forced to deposit its silt on the benches above so that the water can come into the reservoir itself comparatively pure. The reservoir under those conditions would be comparatively permanent. It would last two or three hundred years if the silt above were cut off.

The CHAIRMAN. What would be the probable cost of that?

Director POWELL. I have not the figures before me at the moment and I dare not speak from memory. I have the figures at my office. The construction of the reservoir might be the minor cost. The right of way might be the major cost, because two railroads run across the site.

Senator REAGAN. Regarding the exhaustion of the waters of the Rio Grande, the people tell me that during the flood season the Rio Grande is very great in size.

Director POWELL. It is.

Senator REAGAN. And that it carries a great volume of water. Is it likely that that water could be so stored that it would not flood the country?

Director POWELL. In my judgment it is likely that that can be done in time. It is my belief that it is possible to store all the waters of the Rio Grande in lakes; cut off all the tributaries from Colorado down to the Texas line; and if all the tributaries are cut off and the water of every tributary is stored there is very little water for the valley of drifting sands. But that will not be done to-day or next year. It may be twenty years before all the water is stored. If, however, irrigation should develop for twenty years as it has developed for the past two years in that country the water will all be cut off in less time, that is, all the flood waters of the dry season.

Senator REAGAN. If storage would do they might get the waters of the wet season and hold them over for the dry season.

Director POWELL. Yes, that will ultimately be done, to some extent.

Senator PLUMB. When you say "season" do you mean "year?"

Director POWELL. Yes, I mean the dry year. I think the waters will be ultimately stored in that region. They are already in that region providing reservoirs to store the water and hold it over from the wet year to the dry year.

Senator CASEY. Have you formed any estimate as to the number of dry years in a number of given years?

Director POWELL. They will come pretty evenly. There will be two or three or four years dry, and two or three or four years wet; not invariably so, but frequently so.

I place before you to-day a map of the Rio Grande, including all the area drained by that stream north of the Texas line. There are some important facts relating to the utilization of the arid lands which can be well elucidated by considering that region of country, and I present the map again for that reason. In talking to you about the irrigation problems presented in the valley of the Arkansas, I called your attention to the fact that that valley could be divided into districts, each one an independent unit. The whole arid region may be divided in like manner into natural districts or drainage basins, each one of which has its problems so interwoven that the entire district must be so considered in planning its system of irrigation works, but which is practically independent of all other districts. These hydrographic basins, as I call them, are of three classes, viz, headwater districts, river-trunk districts, and lost-stream districts. The headwater districts commence in the mountains and extend down the streams far enough to include catchment areas and farming areas. These headwater districts are not only found on the main streams, but on all perennial laterals or tributaries. Usually each lateral or tributary forms a natural district by itself. But the great rivers flow on across the plains and down the great valleys, and their trunks must be divided into districts, each one of which presents an independent system of works. These I call river-trunk districts. Then in the arid lands there are many streams which do not flow into great rivers and ultimately to the sea, their waters being lost in the sands or emptying into salt lakes. These I call lost-stream districts. All of these classes are represented in the Rio Grande region, the map of which is before you.

In considering this subject and planning the work of the Irrigation Survey, it has been found that a natural district or hydrographic basin must be considered as a unit in which all the problems must be solved. In order to report upon the district and recommend a plan of works, we must know in such a district how much water will be supplied for irrigation where the diverting dam sites, reservoir sites, and canal sites are situate and where the lands to be irrigated lie. And it has been found, after a careful examination and from the best data we have on hand, that there will be two or three hundred such districts in the arid region, and that if the survey is carried out it will need a separate report on each. I have therefore found it necessary, for the administration of the Survey, to consider these hydrographic basins, and have been studying them for some time—in fact for years before the survey was organized, for I early recognized that ultimately these natural features would present conditions which would control the engineering problems of irrigation and which would ultimately control the institutional or legal problems. The study which I have made in the survey in this direction of course can not be considered final. An actual survey on the ground is necessary to define the limits of each basin, and a very careful survey is especially necessary to define the limits of the trunk districts. The headwater districts, or those of the first class, and the lost-stream districts, or those of the third class, are quite easily discovered; but the districts of the second class require very careful study for their determination. The meaning of this will more fully appear from the illustrations which I am able to present to you to-day in considering the Rio Grande Valley.

First, we have the Saguache River, a river with tributaries—a number of beautiful creeks. The river flows into a sink, and the drainage is lost in the sands. Now, the utilization of that water affects that valley only. It is independent of all the other regions of country. The region of country at the sink is one of sand, and it sinks in these sands and is evaporated. It is only on very rare occasions, many years apart, that there will be a great flood which will cause it to overflow and open a channel to the Rio Grande. In all ordinary years all the water which is used must be in the valley here [indicating], hence it is an independent basin. This is what I call a district of the third class, a lost-river district. It will be noticed that in this district the people who engage in agriculture here can not possibly have any conflict about water rights with the people of any other district. They may use all of this element which they can catch and spread it upon their lands, and nothing will be cut off from any other district; nor can they obtain water from any other district to put upon their lands. And they are interested not only in the water; they and they only are interested in the forests about the fountains whence their waters come, and they are the people who should be interested in the grasses which grow in the valleys and on the hills and mountain slopes.

The Saguache district, therefore, is clearly defined in nature. Its boundary is marked everywhere by the parting of the waters.

Passing over to the Rio Grande proper, we have the San Luis district, which is also a headwater district. The San Luis park is a beautiful tract of land, and high mountains stand around it and gather great quantities of water. This is a region lately redeemed for agriculture, but already all the flow of critical years with extreme dry seasons is used in agriculture, and the companies that are specially interested in these water rights are preparing to store and use all its waters which flow through this season. It may be possible that they can use all and that the area of good land to be cultivated will be sufficient. We do not yet know the amount of water that flows in the streams, nor do we know the amount of good available land. Be that as it may, we are able to state that this great district is a unit, and that it must be considered as such in planning the proper system of irrigation works, and that its people will be as a body interested in the management of its waters, its forests, and its pastures. And they are the only people to be interested except to this extent, that if the waters are not used here they will flow into trunk districts below, to be used there. If the people of the districts below, in New Mexico, could lay an embargo upon irrigation in the San Luis Valley, larger areas in New Mexico could be cultivated, but the loss of water on the way would be such that they would not equal in area the lands that could be irrigated in Colorado. It is therefore manifest that it is to the advantage of the agricultural interests of the country that the people of Colorado who live in the San Luis Valley should be permitted to develop their agriculture to the utmost, and use all the waters that they can put upon good agricultural lands.

The Rio Grande, in crossing the line between Colorado and New Mexico, enters a cañon and flows for about 50 miles through the gorge, and its waters can not be taken out along this stretch. This cañon ends where Taos River, coming from the east, joins the Rio Grande. The Taos is a beautiful stream and all of its waters can be used in its own valley. All that run during the season of irrigation and all that run throughout the year can be stored, so that the waters of the Taos may ultimately be cut off from the Rio Grande.

The region of country on either side of the cañon of which I have made mention—Embudo Cañon—has lava-fields and is not agricultural; but some fair timber grows there and much water comes down into the cañon, so that when the river emerges into the valley at the foot of Embudo Cañon it is a fine stream, and must always be so whatever water is taken out in Colorado above. Some 40 or 50 miles below the river enters another cañon. Between these two cañons lies the valley of San

Ildefonso, into which come some small creeks from the east, and the water of the Rio Grande can be taken out at the foot of Embudo Cañon and spread over the San Ildefonso Valley and make here a river trunk district; or district of the second class. This is a district also well defined in nature. Its catchment area is lava-fields above and mountains on every hand, and its irrigable or farming area is the low valley stretching back from the Rio Grande on either side.

Near the foot of San Ildefonso the Chama enters from the west. The Chama is a large river for that country, and its smaller tributaries drain great mountains, and there are many beautiful valleys scattered about through the region. The lower portion of the Chama runs through a sand plain, and these sands are volcanic ashes which drift and blow into the river and fill it with sediment. The Rio Grande above the mouth of the Chama is a clear, beautiful river, but at the mouth of the Chama it is transformed by the mud of the Chama itself. It then becomes a river of mud and continues such to the Gulf, as it takes up sands along its way. The Chama Basin is another natural basin, having timber lands, pasturage lands, and agricultural lands.

At the foot of San Ildefonso Valley the Rio Grande enters White Rock Cañon and continues its course through a deep gorge for 40 or 50 miles. Along this course its waters can not be used for irrigation. The cañon walls are hundreds of feet, and in some places more than a thousand feet, above the waters. But the high volcanic plateau on the east furnishes a notable amount of water to this stream, and on the west there is a group of great volcanoes from which many beautiful streams flow; so that if all the water should be cut off at the head of White Rock Cañon, there would still come into the Rio Grande, through the course of this gorge, a vast body of water to be used below—water which can not be used elsewhere, as none of the streams above on either side of the cañon have agricultural lands along their courses. But they have great forests. Here some of the finest forests of New Mexico are found. This is the great catchment area for the valley below White Rock Cañon.

Some flood waters will always come down the Rio Grande from San Ildefonso Valley, however thoroughly the country may be utilized, and additional water will be caught in the cañon itself, and so the valley below will have a good supply. White Rock Cañon empties below into a valley which I shall call the Albuquerque Valley. In it lie Bernalillo, Albuquerque, Los Lunas, Socorro, and other towns. Now, all the water that comes out of White Rock Cañon can be used in the Albuquerque Valley, as it may be diverted below the White Rock Cañon and carried out and stored on the flanks of the valley. There is now much agriculture in this valley, and some of it is very ancient. Including the catchment area about White Rock Cañon and the hills and mountains on either side, and the valley where agriculture can be carried on, we have another natural district or hydrographic basin—a district of the second class, or stream-trunk district. Now, it will be seen that all the water to be used in this great valley comes from the mouth of White Rock Cañon. Whoever has control of that point owns that dam site and has the right to take the water out of its natural channel and carry it into canals—has command of all the agriculture of that great district.

I wish to explain further that the people who have settled here have taken out the waters of the Rio Grande and utilized them during the season of irrigation, but they have not yet resorted to storage and the waters which they use are used to very poor advantage. The flood plain or strip of country next to the river which is sometimes overflowed is broad and sandy; the river itself is shallow and is a river of mud, and it is very wide; so it flows into these sands and is evaporated to a very large extent and thus lost to agriculture. Then the people have constructed low-lying ditches near to the Rio Grande and take out the water by a system which is exceedingly wasteful and which is destroyed more or less with every flood. Ultimately they will find it to their advantage to take the water higher up, near the mouth of White Rock Cañon, and carry it out by high line canals and store the surplus in the lateral valleys. By this means the area of agriculture in the valley can be increased five or ten fold.

It is possible to take all the water of the Rio Grande there during the season of irrigation. It is also possible to take out all the water there during the non-irrigating season. If the water for the non-irrigating season is to be stored, you are compelled to take it out there. You can not take it out by the present ditches, for they do not flow on high enough ground; but if a canal is constructed from the mouth of White Rock Cañon, and a diverting dam built there and lakes made—there are good places—all the water could be used in the valley. So, not only is it necessary to take the water out at that one point and utilize the entire flow during the season of irrigation, but it is also necessary to take it out at that point in order to store the water which now runs to waste. So that if the water is taken out at this one point of which I speak altogether, the area of irrigation will be multiplied ten times. But that can not be done without considering the rights of the people who now use some of the water by improvident and obstructive dams.

Off to the east here, as you see on the map, is the Santa Fé Creek, on which the city of Santa Fé is situated. It also constitutes a distinct basin with irrigable lands, timber lands, and pasturage lands, and all its waters can be caught and used in the Santa Fé Valley, so that no considerable amount will ultimately flow from the Santa Fé Creek into the Rio Grande.

On the west we have the Jemez River, where another natural district of the first class is found. The Jemez River drains the Tewan Mountains and plateau. The catchment area is well wooded. Fine forests are found and great mountain meadows are seen, but the land above is cold and is not valuable for agriculture, except for pasturage, and perhaps a little hay may be cut with advantage. The many streams which head in the Tewan Mountains and plateau find their way into deep cañons. On leaving the mountains nearer Jemez Pueblo the whole body of the stream can be taken out and put on the mesa above Albuquerque, or west of Albuquerque and Bernalillo. It is another natural hydrographic basin of the first class.

Below Albuquerque we have the Rio Puerco. All of its waters can be used in the upper portion of its valley, and there is much more land than the water will serve. Very little water ever runs into the Rio Grande from the Puerco, and that comes only at flood-time. It is a hydrographic district of the third class, with irrigable timber and pasturage lands, and with many fine sites for reservoirs.

Where the Albuquerque district should end and the next district embracing the Mesilla Valley and the El Paso Valley should begin, I am not able to state, but from such information as I have been able to collect, I believe that below Socorro a new natural division can be made.

Let us go on to consider the region of the Rio Grande below, from Socorro to a point on the river 30 or 40 miles below El Paso. Here there are two valleys, Mesilla Valley above El Paso and the valley below, a part of which is in the Republic of Mexico and a part in Texas. Now it is possible to cut off from these two valleys all of the waters which flow during the season of irrigation in critical years and destroy all the agriculture in those two valleys unless the waters of the non-irrigation season are stored. During the non-irrigating season large bodies of water come into the Rio Grande from the mountains on either side. There are high mountains to the west and high mountains to the east, but there are few perennial streams, and they are only small creeks. The principal body of the water comes in as storm water. But the area is pretty large and its waters can be stored immediately above El Paso and at the head and along the flanks of the Mesilla Valley. At the Point of Rocks, at the head of Mesilla Valley, all of the waters of the Rio Grande can be captured again and they can be taken out into the Mesilla Valley and used once more.

The waters of the non-irrigating season can be stored on the flanks of the valley, and there is more land than all the waters will serve. Still there is a mountain catchment area on either side of the Mesilla Valley, the waters of which will flow through the valley at El Paso at flood times, and these waters can be stored to be used in the valley below in Texas and Old Mexico. But I do not think there is enough of these waters to support all the agriculture now developed if the waters of the Rio Grande are all taken out at the Point of Rocks. To maintain the irrigation now developed in the El Paso and Mesilla Valleys, some division of the waters must be here made. The catch from Socorro down, coming from the mountains on either side, and the surplus which may come down in great floods from the Rio Grande above, must be divided between the Mesilla Valley and the El Paso Valley to maintain the agriculture already established and to give some development to the same. Just how this can be done to advantage is not known; the topographic survey has not proceeded far enough. We know where the waters can be stored for the El Paso Valley, and I have already explained that to the committee some days ago. We can create a great reservoir with reasonable economy immediately above El Paso; we can also create a reservoir, or series of reservoirs, in the Mesilla Valley; but how much water can be caught and held in these reservoirs we do not know, and can not know until the topographic survey is completed, for on that we depend to determine the water supply.

It is safe to say, however, that the reservoir at El Paso may be constructed, and I incline to think that the rights to the present irrigation in the Mesilla Valley may be maintained, the rights in the El Paso Valley maintained, and that irrigation in both districts may be increased—but to what extent and to what size these reservoirs should be constructed is yet unknown. It will require another year's survey to determine these facts. This, however, is certain, that there can be no development of irrigation in these valleys through the use of the waters of the irrigating season only; in fact the present agriculture can not be maintained unless the waters are stored. The irrigation already developed in Colorado and the upper valleys of New Mexico is destroying the agriculture here. Two more years of development will cut it all off when dry seasons come. The only hope for these valleys is through storage, and how the entire problem is to be solved by storage is not yet known. Nor can it be done without some interference on the part of the United States. If the General Government does not step in and by definite legislation assign specific waters to El Paso and the Mesilla, the El Paso Valley will surely be destroyed, and the Mesilla Valley can be almost ruined by the people of the Albuquerque

Valley. What is needed is the construction of storage reservoirs and their protection, and the assignment of specific catchment areas to those reservoirs. The Government must say that a certain catchment area can be used for the Mesilla Valley and that the remaining catchment area can be used for the Albuquerque Valley.

A State, a Territory, and a foreign country are involved, and they can not settle the problem for themselves. There is only one way to protect this ancient irrigation in the El Paso and Mesilla Valleys and their right to use the water of the irrigating season, and to proceed as they have heretofore done without storage, and that is to destroy all irrigation in Colorado and all of the lately developed irrigation in the valley of the Rio Grande in New Mexico above, and to prohibit forever the use of the waters there; and this would mean that to maintain seventy-five to one hundred thousand acres of agriculture, several million acres of development must be stopped. Of course this can not be done. They must resort to storage, and somehow storage rights must be fixed and maintained.

The area drained by the Rio Grande above El Paso is a little more than 23,500,000 acres, or about 37,000 square miles. But much of the region is mountainous. Even if there was water enough it would not be possible to irrigate one-half of the land; of the arable lands only a portion are irrigable, from the fact that there is not water to supply them all. It may be that when all the waters of the Rio Grande are used in Colorado and New Mexico and in the valley of El Paso, in Texas, and the Republic of Mexico, from three to four million acres can be cultivated; but this can be done only by using all of the waters and storing all those that now run to waste. And then the irrigable lands must be properly selected, so that the waters can be used to the best advantage. That none may be wasted they must be stored where there is the least evaporation, and the lands must be selected near where they are stored, and the waters must not be permitted to run through sand valleys, where they are evaporated. They must be taken out from the streams and stored to the best advantage and used without waste. Then it may be possible to irrigate from three to four million acres. Of course the estimate is rough, because the surveys have not been perfected, and it may be too great; I do not think it is too small. Now the problem which you ask me to solve is this: How can these waters be used to the best advantage; how can they be divided among the best lands; and how can the rights of the present irrigators be maintained? I shall try to answer these questions, and certain collateral problems that are involved; and to do so, shall go over the the ground again, district by district.

Commencing then at the head of the Rio Grande Valley, we first meet with the Saguache. This river sinks in the sands; except in very great floods it discharges no water into the Rio Grande. Its valley therefore is an independent district, one of the minor class; all that can be done in the Saguache district is to select the best irrigable lands and provide that the waters shall not be used where they will be largely wasted.

Then we have a district drained by the headwaters of the Rio Grande—a district of the first class. All or nearly all of its waters can be used within the district on good lands, but they must be selected or the waters will be wasted. The district lies wholly within the State of Colorado.

The next district below on the river is the San Ildefonso. This is a trunk district and thus belongs to the second class. For 60 miles down below the Colorado line the river can not be taken out, as it runs in a cañon. The lands on either side are of little value and should be used only for pasturage and forest purposes. This upper portion of the San Ildefonso Valley is naturally the catchment area for the waters to be used in the valley below the mouth of Embudo Cañon. There are some creeks that come into this valley from the mountains on the east. This district, therefore, has a great catchment area which will supply a large quantity of water, which should be dedicated to the use of the farmers of the valley below. But they should understand that they can not maintain rights to use water coming from the San Luis district; that they should develop their agriculture wholly from the supply of their own catchment area. The best lands lie on either side of the river in the valley below Embudo Cañon and along sections of the eastern tributaries. These lands should be selected in sufficient amount to use all the water for irrigation, then there could be no controversy about the water rights in the district. Settlers could not go upon the non-irrigable lands and illegally take the water; farming could be developed in the valley to the greatest extent and on the best lands, and the farmers would be secure from depredation by other farmers going above them and pirating the water—to use a term common in the western country.

Midway in this district, and at the head of the irrigable lands, the Taos joins the Grande. It is a fine stream and its drainage basin constitutes a district of the first class. All the waters of the Taos can be used in its own valley, and it should be established that the people of that district have a right to use all of those waters, and that the people in the San Ildefonso Valley below can never maintain the right to have those waters flow down to their valley; that the Taos Valley is not a part of the catchment area of the San Ildefonso Valley.

In the lower part of the San Ildefonso Valley the Chama joins the Rio Grande. The basin drained by this river constitutes a district of the first class. All its waters can be used at home, and it should be established that the people have a right to use them there, and that no right can be maintained to the use of its waters outside the district.

At the foot of the San Ildefonso Valley the Rio Grande again enters a deep cañon for a course of 50 miles. Along this course it receives many important tributaries that drain high mountains, and on these and timber region, and is a catchment area for a district below. The irrigation can not be practiced to any advantage. It is a pasturage cañon is known as White Rock Cañon. At its mouth the waters can be taken out again and spread over a large valley. In this valley there are already a number of considerable towns. Albuquerque is the principal city, and we will call it the Albuquerque Valley, and the district, including the valley and the catchment area above, the Albuquerque district. It is, of course, a trunk district, and hence belongs to the second class.

Now, it should be established that the people of the Albuquerque district can not maintain rights to use water not caught within their district; that all the volume of the Rio Grande in the San Ildefonso above belongs to the people of that valley; that the only waters which the Albuquerque farmers can use and permanently maintain rights to are those falling from the heavens over their district. The irrigable lands of the Albuquerque district are in excess of the water supply. The nearer to the mouth of the White Rock Cañon they can be used, the greater the area that can be irrigated. Perhaps this district should terminate at Socorro. Perhaps it should go down to San Marcial. A careful topographic and hydrographic survey is necessary to determine this boundary. The district would, at any rate, be more than 150 miles in length, and it is a long sand basin. If the irrigable land should be selected in the southern end of the district, much of the water would be lost on its way; if it is selected in the northern end of the district, this water could be saved. The Rio Grande will irrigate 200,000 acres in the northern end of the valley. But there are lands already irrigated in the southern end of the valley and their rights should be maintained, at least until they are justly extinguished. Doubtless this will ultimately be done. It is of prime importance that no more rights be established in the southern region of the district.

To the east of the White Cañon lies Santa Fé Creek. It is a beautiful stream of water and the region which it drains forms a district of the first class. Here the city of Santa Fé is situated, and the waters of the great creek are all used in irrigation during the summer months. An attempt has been made to store water, but it has proved a failure. The site of the reservoir was among hills that had been denuded of their forests and grasses, and the reservoir was destroyed by the enormous and rapid accumulation of debris. Other and better reservoir sites have been found where the forests are not yet destroyed. The farmers of the district should have control of these forests, or they can not greatly increase the area of irrigation in the district. The lands to be irrigated lie on a plateau in the neighborhood of the city and are already of great value. The principal catchment area is in high mountains where there are extensive forest lands and where there should be pasturage lands, but these are largely destroyed by over-feeding. The pasturage and timber lands greatly need protection in the interests of agriculture below.

Just above Bernalillo the Jemez joins the Rio Grande, and here we have another district of the first class. The Jemez now discharges a part of its waters into the sand, for there is a long stretch of dunes extending from Cia down to the Rio Grande. Still the river has a volume sufficient to carry part of its waters over the sands and discharge them into the Rio Grande. The catchment area is the Tewan Mountains and the Tewan Plateau, a lofty region covered with beautiful forests and the rich grass lands yet uninjured by fire or over-feeding. The mountain meadows are abundant and beautiful, and the forests are among the best in New Mexico. The lands to be cultivated by this river lie on the mesa west of the Bernalillo and Albuquerque. The waters can be stored in the mountain meadows and elsewhere very cheaply, but it will be expensive to take the water across the sand dunes on to the irrigable lands of the mesa. The mesa itself and the catchment area both should constitute one district. The waters of the mountains should be attached to the lands of the mesa, and the right to use the water should permanently inhere there. The settlers in the valley of the Rio Grande should not be able to acquire rights to the waters, for in so doing they will be chiefly wasted. The catchment area is a volcanic district, and volcanic cinders and ashes abound; and these conditions make it necessary to carefully protect the lands, otherwise they will sink the streams and fill the reservoirs. The forest area is, therefore, chiefly valuable as a catchment area, and which should never be denuded of its trees.

The next stream is the Puerco, which comes in below from the west. It heads in the Nacimiento Mountains, on the western slope of the Tewan group. Along this range of mountains there are several beautiful streams that flow into a distant valley into the channel of the Puerco and here land in the sands and pass only in extreme floods into the

Rio Grande. Practically it is a district of the first class. Its waters have been used in irrigation in the settlements near the mountains, which are, to some extent, well situated for such purposes. But farming is chiefly carried on in the valley of the Puerco, and in that region can not be permanently maintained to advantage. The rights to irrigate so far from the mountains must be permanently extinguished if the Puerco is used to the best advantage. The catchment area is the slope of a great mountain range covered with fine forests, and there are many good reservoir sites. The pasturage is also extensive, but the pasturage and the forests must be protected to save the agriculture. The irrigable lands of the Puerco should be carefully selected and no other lands should be cultivated. The reservoirs must be selected in the valleys and on the slopes of the mountains, where they will be subject to destruction by silting if the forests and grasses are not carefully preserved.

From Socorro southward to El Paso is a distance of about 200 miles by the river. There is already irrigation in the Mesilla Valley above El Paso, and there is also much farming below El Paso in Texas and the Republic of Mexico. Through much of the way from Socorro to the head of the Mesilla Valley the river cañons again and there is a natural catchment area for the country below. This upper region should be declared the catchment area for the Mesilla Valley. At the mouth of this cañon there is a place called Point of Rocks, near Fort Selden. Now it is possible to take out all the waters of the Rio Grande derived from the catchment area above, which has already been described at this point, and there is land enough in the Mesilla Valley to use it. But this would cut off all the water from the El Paso Valley below. There is a short pass or gorge just above El Paso through which the Rio Grande runs. This divides El Paso Valley from Mesilla Valley. To maintain the rights of the present irrigators in Mesilla Valley and El Paso Valley alike, it becomes necessary to unite these two valleys into one district, and to divide the waters between them. There is water enough coming in the catchment area described to maintain all the agriculture yet developed and to increase it somewhat. How much we do not know, as the survey is unfinished. Nor do we know how to divide the waters. The El Paso Valley is partly in Texas and partly in the Republic of Mexico. The Mesilla Valley is in New Mexico. It is thus that the waters of the Rio Grande in this district must be divided between three peoples, and unless some authority steps in and makes this division the irrigators of the Mesilla Valley can take all the water and destroy all the farming below in Texas and old Mexico.

The survey has developed the fact that we can store water with reasonable economy and in sufficient amount immediately above El Paso, at the gorge of which I have spoken, to supply the wants of all the farming in the valley below in both countries, and from the same reservoir an additional area can be served; but there is no wisdom in constructing this reservoir unless steps are taken to provide a catchment area for it, and to protect that catchment area from spoliation. It is thus that the El Paso problem can not be solved by the construction of a dam at El Paso and the establishment of a reservoir to hold water for the valley below. A catchment area must be provided, and on providing this the rights of the Mesilla Valley must be maintained. It is true that if the dam is constructed at El Paso now flood waters in sufficient quantities will come down to serve present wants, but these flood waters can be caught above and ultimately will be caught above, and it would be unwise to pay no heed to the ultimate conditions.

How many years ere this will be I do not know. It will depend upon the rate of development, an uncertain factor. But schemes have been projected and begun in the Rio Grande Valley within the last eighteen months to take one-half of the ultimate supply of water. Most of these schemes have been projected without any proper consideration of the conditions to be met in order to utilize the greater amount of land. If they are completed and rights finally established on the ground selected, then one-half of the value of the Rio Grande Valley is forever destroyed. The rights and interests thus established will be so wasteful of water that the Rio Grande will sustain only one-half of its possible population. This statement is very conservative. It may be and it is even probable that the water will be able to do only one-third of its duty. And the Rio Grande is a fair illustration of the facts and conditions pertaining to every great river on the arid lands.

This, then, is needed in the Rio Grande Valley, that its agriculture may develop normally and that all rights established may be maintained. In each district the catchment area and the irrigable lands should be determined and defined. To define the irrigable lands it is necessary to measure the waters, in order to discover how much land can be used. Then the irrigable lands should be declared such, and the law should prevent any other lands being irrigated. Then the catchment areas should be defined, and settlement on the catchment areas for agricultural purposes should be prohibited, and the people farming on the irrigable lands should have a right to control the catchment areas and to protect and use the forests and grasses. Then, in each district the storage basins should be segregated and reserved from sale and occupation, so that they may not fall into the hands of speculators, whose rights would have to be purchased before the waters were stored; but the people who live in the district, as a body politic and corporate, should have a right to control these storage basins for the common use. The dam sites and the canal sites ought in like manner to be designated and preserved from sale to individuals and held for the common use of the people. By this plan the irrigable lands would be held in severalty by the people; the sites for reservoirs, canals, and dams, and the catchment areas would be held in common in such district. But in the El Paso district, in which the catchment area is in New Mexico and the Mesilla Valley, and a part of the irrigable lands in New Mexico and a part in the El Paso Valley of Texas and Old Mexico, some means must be provided to divide the waters. It is an interstate and an international problem; but the rights of all of the people now cultivating the soil must be maintained.

To define the districts, a topographic survey is necessary; to define the catchment areas and irrigable areas, and to select the reservoir sites, canal sites, and dam sites, a topographic survey is necessary; to divide the waters, a hydrographic survey is necessary, and a hydrographic survey is based upon and can be most economically made through the agency of a topographic survey. In selecting the lands in the headwater districts, they should be taken in regions low enough to have a good agricultural climate. In the trunk districts the land should be as near to the points where the waters are taken from the rivers by diverting dams as possible, that these lines may be the shortest and that the least water may be wasted. The reservoir sites, other things being equal, should be selected on the highest lands, where the evaporation is least. As far as possible, reservoirs should be maintained at the least cost and where the danger of destruction is least. The principal lines of canals should all be designated in advance, in order that impedimentary and obstructive rights may not be established. These obstructive rights are of two classes. First, where a lateral stream joins a main stream, the waters of the lateral should be taken to lands sufficiently high up its course to be out of the way of the development of irrigation on the principal stream.

The principal stream usually has a lower gradient, and its waters can not be taken to very high lands; and if the waters of the lateral stream occupy the low lands, the waters of the principal stream can not be used. This condition of affairs has arisen in many cases already in the development of irrigation in the West. The obstructions of the second class relate to low line canals taken out along the course of the stream which runs in a sand plain. If the canals are taken out here, the whole length of line is extravagantly great, and the loss of water is correspondingly great. All canal lines which relate to the utilization of water for irrigation and to the development of agriculture in arid lands—they are all of great importance; no one can be neglected without doing serious injury to agricultural industries. If these things were done in advance of more dense settlement, and then the people permitted to control their affairs in their own way—divide the water among themselves in each district as they please, protect and utilize their forests in obedience to their own judgment, corrected by experience as time goes on, use the pasturage for their flocks and herds, and protect it from destruction that they may thus use it, the arid lands would furnish homes to prosperous, peaceful, and happy people.

Senator PLUMB. Are you going to deal with the question of the underflow or subdrainage? I wish to ask you some questions in regard to that.

Director POWELL. I am ready to answer any question at once, so far as I am able.

Senator REAGAN. That subject will come in better order when he comes to discuss the Gila River.

Senator PLUMB. Very well.

Director POWELL. The Gila heads in the mountains in the eastern part of Arizona and in New Mexico, but the main part in northern Arizona. Running along this line in Arizona there is a line of cliffs rising from 2,000 to 5,000 feet high, so that the region above is from 2,000 to 5,000 feet higher than the region below. This [indicating by the map] is the plateau of Arizona and this the lowland of Arizona. There is a general difference of altitude of 3,000 to 5,000 feet. The streams all head on this plateau or in these high mountains, and as they flow westward, to unite with the Colorado, every stream becomes generally less and less, so that while there may be in dry seasons a great body of water coming from the plateau and the mountains and there may be scores of beautiful creeks and some small rivers that are perennial (even in the dry seasons), yet in dry seasons the low part of the Gila will be a series of sand hills. (See map.)

Senator CASEY. In the dry season of every year?

Director POWELL. It is only in the very wet years that there is water running in the Gila during the dry season.

Senator CASEY. The dry season of the average year?

Director POWELL. In the dry season of the average year the lower Gila is dry. The rain-fall above is 20 inches or more, and in the mountains it may be 24 inches in some places. Below, the rain-fall is from 3 to 10 inches only.

Senator PLUMB. Where does the rain-fall come from in that region? Is it from local evaporation?

Director POWELL. Partly so, but in the main most of the moisture of this region comes from the Pacific Ocean and Gulf of California, though it is used over and over again. It is evaporated and then falls, is again evaporated and again falls, and so on. It is used over and over again in that manner as it passes eastward with the great upper currents of air.

Now, in all these mountains and cliffs from which beautiful streams run out many are found which never reach the Gila at all.

Senator PLUMB. Is that not a feature of mountain drainage everywhere, as in the upper Rocky Mountain region, for example?

Director POWELL. It is common but not universal. It is a special feature of this region.

Senator PLUMB. I have seen many streams in the Rocky Mountains that were rushing torrents for 3 or 4 or 5 miles and then disappeared entirely.

Director POWELL. Yes; but I will show you where nearly all those occur. They nearly all occur in this great basin lying around here [indicating by reference to the map]. That is the great region of lost streams. Within this region there is no drop of water that runs to the sea—the region colored green and olive on that map. All of the water is lost.

Senator JONES. Is there much rain-fall in that region?

Director POWELL. It varies from 3 to 16 inches.

Senator PLUMB. Is it carried by subterranean streams?

Director POWELL. No; it is all evaporated.

Senator PLUMB. Then that is not aided by the moisture carried there, but is simply evaporated and falls again?

Director POWELL. It gets a good deal of moisture from the west. Moisture evaporated in this region [indicating] is carried over on to the Rocky Mountains here. The progress of moisture across the continent from west to east is by steps. It is precipitated and evaporated, and again precipitated and again evaporated, and passes across the continent in that manner, by steps, and it is chiefly thrown down on the mountains.

As to the Gila drainage basin—the lower portion of the Gila is a region where the mountains gather the main part of the moisture, and where these waters flow down and are lost in the sand, ultimately to be evaporated; so that the irrigation of the Gila region depends on three things: First, the utilization of the running streams abounding in these mountains and along Salt River, and streams which head in the mountains. Secondly, it depends upon the utilization of the storm waters; less than one-half of the mountains of the region give rise to living streams. The streams of the mountains of the lower land are in the main intermittent streams. When the rains of the spring start the streams start and run out to the valleys until they are lost, and when the dry seasons come all the streams of the mountains dry up and the waters roll down into those lands and can be recovered in various ways, but in the main, in that country, in part by artesian wells and in part by wells that must be pumped.

While on that subject I will say that the pumping of water from wells is a peculiarity of American industry. I never appreciated its magnitude until this past season. This fall I sent Mr. Nettleton to Spain to investigate some questions. He has just returned, and tells me that there is nothing in France, in Italy, or in Spain to correspond with the industry growing up in this country by the use of pumps for the recovery of water. American genius has done this; it has invented pumps that can be run so cheaply and of such power that it is possible, at an expense of $200 or $300, to irrigate a good farm in any part of the country where good wells are found, by the use of pump-water.

Senator **Casey**. The pumps being run by steam?

Director **Powell**. By steam one way or another.

Senator **Casey**. And it is in this region that they are using those pumps?

Director **Powell**. In this region they are beginning to develop the pumping process.

Senator **Plumb**. You saw some of those pumps in operation in Colorado this past year, did you?

Director **Powell**. Yes.

Senator **Plumb**. Did they seem to be successful there?

Director **Powell**. Very successful.

Senator **Plumb**. Not only on the ground of work but of expense?

Director **Powell**. Yes. They have made the expense trivial. A boy or a woman can run such pumps. They are very simple.

Senator **Jones**. Did they not say they had some pumps in operation to which they sent somebody only once or twice a day to look after them?

Director **Powell**. Yes, they sent somebody to feed them once or twice a day.

The genius for invention has solved the problem for the irrigation of a very large district of country in this Southern region, which is of great importance for this reason: that is the region in America of the highest temperature, the region where the date, the palm, and the orange grow, and where cotton and sugar can be cultivated, and all the products of a subtropical climate grown.

The **Chairman**. Would not that remark apply to the places east of the Rocky Mountains in Kansas and Nebraska where the waters are lost?

Director **Powell**. Yes; but there are few countries where it is lost as it is there. It is lost in the valley of the Arkansas and in the valley of the Platte and in many other places, but there is only a portion lost there, while here it is wholly lost, and the people will have to depend upon the lost water entirely for irrigation or the region will be absolutely desolate.

The **Chairman**. They have some irrigation in the Salt River Valley.

Director **Powell**. Yes, on the streams above, as I have explained.

Senator **Reagan**. The mountain streams all dry up in that place?

Director **Powell**. Yes.

Senator **Reagan**. But you remember that it was a dry season when we were at Phœnix?

Director **Powell**. Yes. I excepted the Salt River and Gila River regions in what I have been saying. All through California and around here [indicating] there are short north and south ranges, which do not rise very high, which furnish no perennial streams. It is in that region of country that they must depend on pump-waters for irrigation, and to some slight extent on artesian waters.

Senator **Reagan**. Senator Plumb made an inquiry about the under-streams that flow through the sand. If you remember, some witnesses had a good deal to say to us about there being underground rivers in some places.

Director **Powell**. Yes. If you wish me to talk on that subject I shall be pleased to explain the matter.

Senator **Plumb**. If you have finished with what you wished to say about the surface waters I shall be glad to ask you some questions about the other.

Director **POWELL**. I shall be glad to answer any questions.

Senator **PLUMB**. In your judgment is this under-deposit of water a standing body of water merely, or is it a flowing stream?

Director **POWELL**. I do not believe it is a flowing stream.

Senator **PLUMB**. That is to say, is it a great cavity into which those streams flow?

Director **POWELL**. It is rather a complicated question. I will explain it. There are two problems with regard to it. Where the waters disappear in the sand, as they do here in the Great Basin, they spread out in what is known as a "sink." Where they spread out in the sands along a great river, as in the case of the Arkansas and the Rio Grande, the valleys of which descend 4, 5, 6, 8, or 10 feet to the mile, the waters gradually creep down these valleys with a distinct forward movement.

Senator **PLUMB**. And are replaced by waters coming behind?

Director **POWELL**. Yes; but not in the sense that there is a stream or flow of water. The water simply percolates through these sands.

Senator **PLUMB**. That would be important as affecting the quantity of this water?

Director **POWELL**. Precisely.

Senator **PLUMB**. As to whether any of those waters if removed by a ditch would be instantaneously replaced by a pump, what have you to say?

Director **POWELL**. I am very glad you have brought that question up. But let me go on one moment. When you pass the mountains of Colorado along these streams for the first hundred miles there are perhaps only 10 or 15 inches of rain-fall, while on the mountains there is an excess of rain-fall. The water is gathered on the adjacent mountains and precipitated. But when you get from 100 to 200 miles away from the mountains the attraction of the moisture is not to the mountains, but is again eastward, and again the precipitation is greater; so that at some distance away from the mountains you get a greater rainfall than you do nearer the mountains. It therefore requires less water for irrigation there than it does above, because nature supplies a greater share. On the other hand, the snows of the valleys are forever supplying a local rain-fall, and the people do not depend on that which comes from the mountains. The increase of local rain-fall to 20 or 22 inches across that country produces rain-water in the valley much faster than it can be pumped out. The quantity of water is ample, but the supply will come from the adjacent country, and not from above, if the water is used in irrigation above. The lands of the valley will be supplied with water by the storms of the plains.

Senator **REAGAN**. At one place the people described to us an underground river. They said they were putting in tubes farther up and gradually raising them so as to pour the water out on the surface.

Director **POWELL**. It is a good illustration of one of the "sinks" that I have been describing. Here is a river running down from the mountains—mountains on this side and mountains on that—with springs, etc., all gathering into a valley, which at last debouches into a plain below. Right by Tucson is a sink in which the water disappears. If you go into that valley you will find that in one place it opens out quite wide, while in other places it narrows up into a cañon. Wherever it is narrowed by the solid rock you will get a good flow of water.

Senator **PLUMB**. A large portion of the water supply of the city of Denver is derived in the same way. But my idea was to inquire whether that was a deposit of water or a flowing stream. Suppose, for instance, you should take out 50,000 cubic inches of water in a given moment of time, the question is whether this flow of water that is back of it, coming from this hidden source, will immediately replace it?

Director **POWELL**. Such questions are properly answered by experience, and so what I have to say——

Senator **PLUMB**. I understand that, but I thought you had made some observations on it.

Director **POWELL**. I have.

Senator **PLUMB**. There is no doubt about water being there, and no doubt as to the possibility of getting it out, because the average slope in western Kansas is about 7 feet to the mile, while 2 or 3 feet is sufficient for that purpose.

Director **POWELL**. My judgment is this, that the supply of water is permanent; that it is permanent by reason of the storm-waters of that region, which are great. Many times in the last twenty-two years I have been over that ground and witnessed storms. When the rains do come the sheet of water that comes down from the adjacent hills is enormous. I am confident the source of water is perennial for that reason, even though the waters of the river should be cut off in Colorado.

Senator **PLUMB**. That is to say that acts practically as a reservoir for the storm-water?

Director **POWELL**. Yes; and on the other hand I do not believe that the supply is inexhaustible. I believe there is a limit to it.

Senator **CASEY**. It might be carried off by constant drainage. You have often seen water where the drainage is constant and where the water, although very full at one time, becomes exhausted.

Director **POWELL**. As to that section of the Arkansas River that runs through the State of Kansas and has a valley several miles in width, I believe that a large area can be redeemed by irrigation by the use of its underground water, yet I believe it has its limits.

Senator **PLUMB**. You think that the taking away of the water will have the same effect underground as it has on the surface streams, that is to say, it will dimish the supply below?

Director **POWELL**. Yes; that is to say you can not irrigate illimitably with it, but it will irrigate perhaps two or three hundred thousand acres.

Adjourned.

SECOND DAY'S SESSION.

WASHINGTON, D. C., *January* 21, 1890.

The committee met pursuant to adjournment. Present, Messrs. Stewart (chairman), Casey, Jones, and Moody.

FURTHER STATEMENT BY DIRECTOR POWELL.

The **CHAIRMAN**. Major Powell, you may resume your statement.

Director **POWELL**. Mr. Chairman and gentlemen of the committee, I propose rather briefly to review some facts relating to important drainage basins, and to continue the statement which I was making at the adjournment of the last meeting of the committee, but in the main I shall omit the engineering problems and confine myself more exclusively to the problems of civil administration.

The next basin in order, continuing from the point where I left off at the last meeting, is the drainage basin of the Colorado.

The Colorado is one of the great rivers of the continent, being more than 2,000 miles in length. It runs in the main from north to south and from highlands to lowlands, so that it passes in its course through many climatic zones. It heads in the Wind River Mountains and drains a large region in the Territory of Wyoming. It also drains a portion of Utah and a portion of Colorado. The regions drained in Wyoming are very cold, because they lie at a great altitude. All the lands in Wyoming that can be irrigated by the tributaries of the Colorado or Green River are lands valuable mainly for the cultivation of potatoes, hay, oats, and perhaps rye. In some few of the low places wheat may be cultivated. But I will designate for our purposes at the present time the potato zone of the Colorado.

Following down the Colorado to the lower regions in Utah and some few valleys in the State of Colorado we get into a region where wheat is cultivated, but the areas that can be redeemed along the Grand and Green Rivers for these purposes are not very great. Still farther down the Uintah Valley, in Utah, and the Grand River Valley, in Colorado, corn may be cultivated. There are some minor valleys for the next 700 miles along the Colorado that can be used for the cultivation of corn.

More than four-fifths of the upper drainage basin of the Colorado lies from 5,000 to 8,000 feet above the level of the sea. About the rim of this basin stand the Wasatch and Uintah Mountains on the west, the Wind River Mountains on the north, and the great Rocky Mountain system on the east; all that vast area, as shown in the map before you, is all drained into the Colorado River.

As there are great gorges from 200 and 300 feet to 5,000 feet in depth, in general the streams run so far below the surface of the country that they can not be used for agriculture. But nearer to the mountains, on each side, there are high valleys in the potato region that I have described.

In the regions below the cañons, at the mouth of the Grand Cañon, as it is called, the Colorado falls into a great valley, across which some mountains stand, but in the main it is a low and very warm valley, and a region where rice can be cultivated. And throughout the world the great rice regions in general are where irrigation is practiced. In this valley ultimately rice and the vegetables and fruits of that zone can be cultivated in great abundance. On the lower Colorado there may be cultivated to advantage, also, cotton, sugar, and especially the date palm, because the country is far to the south and low.

Now these are the problems involved in the civil administration: A part of the waters are in Wyoming, a part in Colorado, a part in Utah, a part in Arizona, and a part of California, and they are to be divided between those States and Territories. But there will be no difficulty in dividing them in the upper regions because the land which can be covered is less than the water will serve. So that all the upper region of the Colorado that can be irrigated may be by the streams, and there will arise no necessity for a division of the water between States, counties, districts, and people. But when we come to the lower portion of the Colorado there they will have to be divided. A small portion of Utah, of Nevada, and California on the west, and Arizona on the east can use these waters, and after all the waters have been used above, as I have described, after all the region is irrigated that it is possible to irrigate, there will still be a vast volume of water in the Colorado that can be utilized and divided between the States and Territories that I have mentioned. But at the present time there are no means by which those waters can be divided between them. It is probable that 5,000,000, 6,000,000, or 7,000,000 acres of land can be irrigated in this lower region. So that ultimately it becomes a problem of great importance to divide these waters.

Passing then from the Colorado drainage, I will omit some of these minor areas and speak of the Sevier drainage.

The Sevier heads in plateaus in southern Utah and runs northward, then turns westward, where it is lost in the desert. The people of Utah have already taken out the waters of the Sevier below the lower part of the valley to irrigate very large areas, and until within two or three years, settlements have been crowded on the head of the Sevier, and the people above are beginning on the upper portion of the Sevier to take out water from its tributaries, and already they have done this to such an extent as to cut off the water from the farms below. So that the problem now is to divide the waters of the Sevier in such a manner as that there will be no conflict. The people above are taking out the waters of the stream on to land which is of comparatively little value for agricultural purposes because it is cold and in the region designated as the "potato region."

The lower valley of the Sevier is warm, and agriculture is practiced there with great success. But, if the process of abstraction of the waters from above continues, as it has been for two or three years past, much of the water of the Sevier will be cut off and the lower settlements destroyed.

Senator CASEY. What are the people above on the Sevier raising?

Director POWELL. Hay, potatoes, oats, etc.

Senator CASEY. Do they raise any wheat?

Ditector POWELL. No; not that I know of. It is possible that there is a small portion where wheat can be raised, but the most valuable lands are in the lower valley.

I will speak next of the Jordan drainage, the Jordan being one of the upper rivers flowing into Salt Lake, and from which the irrigation of a large tract in Utah is had.

Utah Lake cuts in two the valley of the Jordan. Above, the Provo and Spanish Fork, and a number of other small streams flow into Utah Lake. The waters in these upper streams are taken out to irrigate the valleys they pass through. But not all of their waters are used above; a very large amount, in the season when irrigation is not practiced, flows into Utah Lake. Utah Lake is a natural reservoir for the Jordan. Now, irrigation has been carried on and developed in the valley of the Jordan to such an extent that practically the waters of the irrigating season are already utilized. So that, the development or increase of the area of irrigation in the valley of the Jordan, including the whole valley, is to be made by storing the waters, and they can be largely stored in Utah Lake. But if Utah Lake is used as a reservoir, it must be used in part by cutting down the outlet and in part by damming the outlet so that the waters of the winter may be stored therein.

To do this the lands belonging to people above will be flooded. Already there has been conflict there, but the church authorities stepped in and settled the matter. The last time there was conflict, a committee of arbitration was formed, and each of the two counties involved paid one third of the expenses of the damage, and the church from the tithes paid the other third. They settled the difficulty in that manner. But the difficulty still remains, if any increase is to be made in the area to be irrigated in the valley of the Jordan.

And on Bear River we have another difficulty which is more than an intercounty and intercommunity difficulty. Bear River heads in Wyoming, flows northward into Idaho, makes a great circuit in Idaho, and then returns to Utah, where it ultimately empties into the Great Salt Lake. It is therefore an interstate problem, and the people of Idaho and the people of Utah are now in constant conflict. During the past season the governors of those Territories and their citizens have been petitioning the Secretary of the Interior on the subject. There has been much newspaper warfare about the matter, and meetings and conventions have been held to determine how the waters of the Bear shall be divided. A large portion of the valley of the Bear—the warm and valuable portion of the Bear—lies in Utah. The region drained by the Bear—the valley of the Bear—which lies in the Territory of Idaho is cold. There is a small area of good land, but in the main the lands are grass lands and potato lands, such as I have described. So that there is now pressing upon the Department, Congress, or some authority, the problem of dividing the waters of the Bear between Wyoming, Idaho, and Utah.

Passing to the west side of the Great Basin, I will say one word in general of the Great Basin.

The streams which head in the Great Basin, or drain it, do not run to the sea. So that there are many small streams, like the Jordan and the Sevier, which head in the mountains standing about the Great Basin and are lost in the sinks and salt lakes, and many of them in the sand. Of the several drainage basins in Nevada I shall not stop to speak now, except a few.

Here another problem arises peculiar to the region itself. The Truckee, the Carson, and other rivers of Nevada, head in the Sierra Nevada Mountains within the State of California. The main waters used in the western half of Nevada have their sources in California. Nearly all the reservoirs for the storage of waters of these streams must be constructed in California. The people, therefore, who live on these rivers and depend on irrigation have their sources of supply in another State.

If they are to increase the area of irrigation from these streams—and it may be very largely increased; we have already made the survey showing that a very large amount of water can be stored in Lake Donner, Independence Lake, Tahoe, etc., in California—if the people are to utilize these waters in irrigation on their lands below, they will have to go into another State to do it—they will have to construct their canals and reservoirs outside of their own State. It makes a very serious interstate problem, therefore.

I shall pass hurriedly over all these points simply to bring out hereafter the interstate problems in the main. Perhaps I had better refer to the Humboldt River.

The Humboldt River heads in low mountains in central Nevada from many small streams and springs. It is largely supplied with storm water, so that during seasons of storm a great flood of water rolls down the Humboldt River. During exceedingly dry seasons it is almost dried up. The problem of the Humboldt is, therefore, to store the storm waters immediately along this basin and to utilize the small streams on which they now depend in dry seasons.

We have here the great valley of California [indicating on the map]. I shall make no mention of the waters of the San Joaquin and its tributaries, but wish to say a few words about the waters of the Sacramento.

The Sacramento Valley is a region in which irrigation is practiced to some extent, but in which it is not absolutely necessary. During the last two or three years especially the people of that region have come to understand that irrigation would benefit them very greatly, and they are now developing irrigation in that valley. Ultimately they will use a large part of the waters of the Sacramento for that purpose.

There is a double problem involved here. The Sacramento and its tributaries have heretofore been used for hydraulic mining. When the miners and farmers of this region come to understand that it is wise for them to use the waters of the streams for irrigation, the conflict between the farmers and the miners will cease. The works necessary to utilize the Sacramento for irrigation and the works necessary to utilize the waters for hydraulic mining will be common works, and both parties will be interested; so that the problem that has divided the interests of that valley between the miners and farmers can ultimately be settled to the advantage of both.

The CHAIRMAN. I am afraid that is a little overstated. It will never be settled until they get the gold out.

Director POWELL. Perhaps I had better dwell upon that point a little. First, on the American River and all those rivers used for mining purposes they have learned enough to know that the waters can be stored there. If the waters are stored above in the lateral valley to be used in irrigation below in the valley of the Sacramento, an equable stream can be preserved along the Sacramento. A flood stream need never be allowed to run in the valley; the waters can be controlled in such a manner that floods will not spread over the valley.

The CHAIRMAN. I believe that can be done.

Director POWELL. Then the destruction to the land which is sometimes done in two or three weeks of flood-time will not happen.

The CHAIRMAN. The great conflict is that they have a great many storage reservoirs. They can work these mines with these waters by the hydraulic process, but it will not pay to work them by any other. It is estimated that, in the old river beds which run north and south at an elevation of 600 feet above the level of the sea, there are a thousand millions of gold. That is the estimate of experts based on results obtained prior to the injunctions against hydraulic mining. But in working the mines by that process they cover up the land below and that is the controversy.

Director POWELL. The land is covered in this manner: The streams that are used in hydraulic mining tear the hills down and distribute débris over the low lands—the materials of which the hills are composed. The bowlders and gravel of these hills are carried a short distance, finer material much farther, sand a somewhat greater distance, and part of the material, exceedingly fine, is carried very far down the river and there deposited. The rivers, therefore, run like rivers of mud. That débris accumulates along the course of the river, chokes the river, and forms dams and bars from point to point. So that, when the spring rains come and the snows melt the flood comes down all at once, and, the channels of the river being choked, the flood spreads itself over the valleys, and the débris from the channels of the river bury the land many feet. The Senator knows how that is. I have traveled along there for miles when there was a good stage road and telegraph line, and a few years after along that same road the telegraph poles were buried. Here and there one would have its top protruding above the débris.

Senator JONES. How large an area was covered in that way?

Director POWELL. I remember indefinitely the area that I saw covered from 2 and 3 to 30 and 40 feet in depth, but as well as I can remember—it is several years since I was there—it was from 300 to 400 square miles.

The CHAIRMAN. The Bear and the American Rivers when I first saw them had deep banks—40 or 50 or 60 feet deep. The beds of the streams are now above those banks. The highest estimate is that it has covered up 1,000,000 acres of land. Some have put the estimate higher, to 1,500,000 acres of land. But a great deal of that land has become good again by exposure, and it has helped the land that was back from the river by raising the water-bed and moistening that land. So that what was dry land back of the river has become moistened land. But the farms near the river have been all covered up. The miners were enjoined from proceeding with this kind of mining. There is a vast amount of money in these mountains, estimated by the best experts at a thousand millions, and until these injunctions are removed this gold will never be utilized.

Director POWELL. I pass from California directly to the Snake River or Shoshone River, where some important problems exist. The Snake River has its origin in Wyoming, passes into Idaho, crosses the Territory of Idaho, becomes the boundary line between Oregon and Idaho for a long reach, finally passes across the State of Oregon, whence it proceeds north to Washington Territory, and thence turns westward through Washington Territory until it joins the Columbia.

The Snake is a river of great magnitude. Its waters can be stored in part in Wyoming, in part in Idaho. Lakes have already been discovered as sites for reservoirs, by which a large amount of water, 2,000,000, or 3,000,000 acre-feet—that is, water enough to irrigate 2,000,000 or 3,000,000 acres of land—can be stored at very small expense. That is in the upper part of the Snake River Valley.

The waters of the Snake River must be divided between Wyoming, Idaho, Oregon, and Washington, and interstate problems have arisen in part, and will arise hereafter, of great importance; because it contemplates the irrigation of 6,000,000 or 7,000,000 acres of land.

Senator Casey. What products can be produced there?

Director POWELL. It is a wheat and corn region.

Senator CASEY. Throughout its whole length?

Director POWELL. This is a warm valley, a valley in which it is desirable to live on account of its low altitude; but the upper part of Wyoming is high and cold.

In the utilization of the waters of the Snake arise some problems which are found elsewhere, but which can be stated very well here; and perhaps I had better dwell upon them at this point.

If the waters of the Snake should be taken out at points near together by small canals along the river and used on lands near to the river it will be much easier to develop the first, perhaps, 1,000,000 of acres of irrigation along that river. That is to say, it is possible to construct diverting dams and to take the water out of the river by piece-meal along the river here [indicating on the map] for the irrigation of the first 1,000,000 acres of land. If the water should be taken out high up on the river and carried far back over the valley, an area of four, five, six, seven, or eight times as large as I have mentioned—I can not say exactly how much larger until the surveys are completed—can be irrigated by those waters, and if they are taken out in this manner the cost per acre will be much less than if they were taken out by piecemeal.

But further than that, if it should be taken out piece-meal to irrigate 1,000,000 acres of land, then the rights become vested in irrigation works there, and then they can not go above and take the water out, because it will cut the water out from the people below, and they will have to be bought out to increase the area of irrigation. So that it becomes important, if all the waters of the Snake River are to be ultimately used for irrigation, and many million acres of land redeemed which can be redeemed in this manner, to provide now, before little canals are built along its course, that the Snake be taken out higher in a few places in great bodies, or we shall get into the same condition they are in in the valley of the Nile.

It is estimated that the waters of the Nile, which are now irrigating 5,000,000 acres, will serve three times that amount with an annual expenditure less per acre than it now costs to serve the 5,000,000 acres. But if works are to be constructed and the waters of the Nile taken out from the supplies above on the lands where drainage is not so necessary, it can be done only by buying out the interests on the Nile entirely. The English are now working at this problem of how to meet the necessity now existing and drain the lands that are now becoming swamp lands, and make the annual expenditure per acre much less and increase the area to be irrigated. The problem which I stated about the Snake River appears again and again in all the great streams of this country.

The Columbia River heads in British territory. It is a great river and carries a vast volume of water. After it crosses the boundary line between British territory and our own there is a great valley which can be ultimately irrigated, and there is abundant water which can be used. But a large part of the water that is to be used in the United States can be used only by constructing works on British territory; that is to say, a large part of the area which could be irrigated in the United States could not be irrigated without building works on British territory. But, on the other hand, the problem is not so serious. There is more water than the people of the British territory need.

The Kootenay River, one of the important tributaries of the Columbia, in British territory, flows into the United States and returns to British territory, and there arises an international problem; and so it is with a great many of the smaller streams along the border, streams which I need not stop to mention, where international problems are involved.

Passing over to the headwaters of the Missouri River, we find that the Milk River heads on British territory and flows down into the territory of the United States, and with regard to that river international problems are involved. Beside the international problems on the Missouri River we have these interstate problems: That river heads in Montana partly, in Wyoming in fact, and flows through both the Dakotas southward, so that ultimately there is to be devised some means of dividing its waters between Montana, North and South Dakota, and perhaps a part may ultimately be used in Nebraska. The Big Horn and Powder Rivers head in Wyoming and run northward into the Yellowstone, and the waters of each of these rivers have to be divided between Wyoming and Montana.

The Yellowstone itself presents some interstate problems. The chief storage area of the waters of the Yellowstone is in the National Park.

The Yellowstone Lake is a natural storage basin. In it can be stored waters for the irrigation of 300,000 or 400,000 or 500,000 acres of land. Along the Yellowstone River is an important problem worthy of brief mention here. The Yellowstone has its course through Montana in a deep cañon 400, 500, or 600 feet below the mesa above. Along its course is a valley varying from 2 and 3 to 6 and 7 miles in width. A part of that lower valley is valuable for irrigation; a part is not valuable, and if water were used over the whole of that valley it would be largely wasted. But the mesa lands above are good, and it would be necessary to take the waters of the Yellowstone above this region, high up, and spread them over the mesa lands on each side. The Cheyenne and Niobrara Rivers involve problems between Wyoming, the Dakotas, and Nebraska. The waters are to be divided between those sections, and the people are in conflict. Some very interesting letters have passed between the governors of those localities protesting against the use of these waters, and Congress has been appealed to.

Senator **CASEY**. Between Wyoming and Nebraska?

Director **POWELL**. Colorado and Nebraska, and likewise between the governors of Colorado and Kansas. Then below, along the Cimarron and Red Rivers, we have interstate problems.

I think I have dwelt long enough on this point; but I wanted to bring out the fact that something must be devised by the United States to solve these interstate problems which are imminent—some common scheme for dividing the waters between these States and Territories.

The **CHAIRMAN**. Before leaving that point I wish to ask a question. You spoke of the Missouri and Yellowstone. Have sufficient explorations of the Missouri been made to determine whether that river can be taken out or not?

Director **POWELL**. A very large part of the Missouri River can be used in Montana, a part in North Dakota, and another part in South Dakota. It can be used alike in Montana, North Dakota, and South Dakota. I will only mention here the major streams.

Captain **DUTTON**. The Missouri River can not be taken out below the Great Falls for a distance of 300 or 400 miles.

The **CHAIRMAN**. It will have to be taken out above the falls?

Director **POWELL**. It will have to be taken out above. The Yellowstone, like the Snake River, is a great river, and the ultimate utilization of these waters is to depend upon great canals.

Senator **CASEY**. Can the Missouri be taken out above the falls?

Director **POWELL**. It can be taken out between Bismarck and Helena.

Senator **CASEY**. That is the Yellowstone?

Director **POWELL**. No; the Missouri.

The **CHAIRMAN**. The Missouri has three forks there.

Senator **CASEY**. Can it be taken out just above the Great Falls.

Director **POWELL**. That is one of the questions to be examined this summer.

I will very briefly call attention to another problem—the great plain extending from British territory to Mexican territory. There is a region of four or five degrees in width, on a part of which irrigation is absolutely necessary, and on a part of which irrigation is conditionally necessary; that is to say, some years they need irrigation, while in other years the land can be cultivated without irrigation.

The **CHAIRMAN**. And always beneficially?

Director **POWELL**. And always beneficially. I have a map exhibiting the artesian wells of the arid lands, extending somewhat over the arid area and the plain east of the well-defined arid lands. This map needs a little explanation so that you may understand it.

Artesian wells have been found in great numbers. The geological basins in which these wells are found and known are colored in the main, as this [indicating on the map]. We have here a basin with many artesian wells in it [indicating].

We have another here [indicating]—the Colorado Basin, the Denver Basin, one in southern Colorado, one in southern Arizona, and one in southern California; another basin there [indicating], and those basins, the geology of which is pretty well known, are in Utah. You see them here [indicating on the map]. In addition to this the people have gone out of the basins geologically known and have experimented elsewhere. Among all those experiments are failures which do not appear on the map; but the successful wells appear and are represented by the dots you observe here [indicating on the map]. A dozen or fifteen wells have been found in that locality. Each dot does not necessarily represent a single well, but sometimes a small group of wells. In some places a single well is found and is represented by a dot. (See map.)

The CHAIRMAN. What is that group of wells there?

Director POWELL. That is in Texas, a part in the arid region and a part in the subhumid region.

Senator JONES. Are they flowing wells?

Director POWELL. Yes. I have not put in the non-flowing wells. There are a great many wells used for irrigation which do not flow over the surface, but the waters rise near the surface and are taken out by pumps. They do not appear on this map, however. The region of country of which I speak, stretching through there [indicating], is one of great interest because of the attempts which have been made to settle the country without resorting to irrigation. During the past fifteen or twenty years in many places other attempts have been made to settle the region. But the settlers who have gone in there have in the main left, settled and left, settled again and left, and so on from year to year. The region of country is on that border land which will be forever attempting cultivation without irrigation. But two, three, or four wet years will occur in succession, when agriculture will be quite successful; then will come two or three bad years and they will be disastrous and the people will migrate. Now, however, the people are appreciating the benefits of irrigation, and when they come to realize that irrigation is necessary for permanent success and prosperity the difficulties will disappear. But while the water supply is not sufficient to irrigate all that country, it is sufficient to irrigate large areas.

Now, I speak first of these artesian waters not because they are of the most importance or of greater magnitude, but because the people are looking in that direction more than any other.

The regions of country underlaid by artesian waters are not at all known from a geological stand-point—we can not say to what extent they are so underlaid. But there is sufficient evidence to lead one to believe that artesian waters are somewhat abundant.

A geological survey is necessary in order that the geological basins may be mapped, and then experimentations in the areas thus mapped will confine the work to regions where there is prospect of water, and by experiments in part and by geological examinations in part, it will be possible to determine what artesian waters are found in that region. When they are found they will be valuable for domestic and horticultural purposes. And though the cost of boring wells is large, and the cost of redeeming lands will be comparatively great, greater than the utilization of flowing rivers, yet the great value given the land by irrigation will warrant the expense.

Artesian reservoirs can never furnish waters for agriculture on a scale of sufficient magnitude to be considered as an important source of supply. The amount of waters which porous rocks will supply is always very insignificant compared with the amount necessary for irrigating any great tract of land. More than half the agriculture of the world is dependent on irrigation. Of this, a very insignificant amount depends on artesian wells. There are wells here and there in Europe, Asia, Africa, and America, and in some of the great islands, but altogether they furnish a very small amount of water for agriculture. If all the artesian wells used for irrigation in the world were assembled in Dakota, they would not irrigate a county of land. But there are other serious reasons why the attention of the people of the great plains should not be directed too confidently to this resource. It is the experience with artesian wells everywhere throughout the world that if too many are bored in any basin all are destroyed thereby. In the northern Illinois district, it was hoped that the great city of Chicago could be supplied with water for domestic purposes by artesian wells, but experimentation has proved that, while a few good wells could be secured, a great number was impossible; that the supply of water would be absolutely inadequate for the wants of the city; and so the authorities were compelled to resort to the lake for their supply. Now, to irrigate the site of the city of Chicago would take more water than to supply it for domestic purposes; so that the artesian wells of that district would be entirely inadequate to irrigate an area as large as the city, or perhaps one-fifth or even one-tenth of the area. Some years ago it was pointed out that the city of Denver and the region round about was the site of an artesian basin. The first well site proved to be very valuable, and the desire to secure water for domestic purposes therefrom led to their multiplication. More than three hundred have now been bored, and gradually with the progress of the boring the collapse of the wells has resulted, and now all the wells have to be pumped; there is little or no flowing water from them. These instances might be multiplied all over the world, and the experience of mankind testifies that it would be unwise to encourage the people of any district of country to depend upon artesian waters for irrigation on any large scale for farming. Waters for domestic purposes, for irrigating gardens, and for supplying stock ranches may thus be obtained in many regions, and the supply of water that can thus be furnished is of value; but when considered as a source for agriculture, for the cultivation of fields and large tracts of country, it will always be inadequate; and it is unwise to encourage any people to engage in agriculture on a large scale and depend on irrigation from artesian wells.

For the district of which I am now speaking, extending from the British to the Mexican line in a broad belt across the plains on both sides of the hundredth meridian, the people will ultimately be compelled to depend upon another source of supply, and one so important that in comparison therewith the artesian supply sinks into insignificance and seems hardly to be worthy the mention. I refer to the use of the storm waters. One-third of the agriculture carried on by irrigation throughout the world is prosecuted by the storage and use of storm waters, and the experience of mankind in this respect is replete with lessons that can not be neglected. The region to which this is especially applicable is the sub-humid region. It differs from what I have called the arid region in that it generally has a greater rain-fall, distributed more evenly over the country, as it is not interrupted by great mountains where the precipitation is concentrated, having from 15 to 22 inches of rain-fall in the average year; sometimes more, sometimes less. There are many years when agriculture is prosperous without irrigation; there are others when it fails without an artificial supply of water. Gradually with the progress of agricultural development it is possible to cover the country with storage basins, or tanks as they are usually termed, in which water may be held to be used in seasons of drought. By this means the farmers may be able to tide over the dry years, and farming may be made prosperous and highly remunerative thereby from year to year. It is in this direction that the attention of the people of that region should be turned.

There is another source of water for that country of far greater importance than that of artesian fountains, but far less than that of the storm waters. I refer to sand reservoirs along the channels of the streams, especially of the great rivers. In that region of country the stream valleys are often great beds of sand, into which sinks the water which comes from the distant mountains, and into which sink the storm waters that come from the adjacent hills. Experience in other countries shows that this source of supply is worthy of consideration, and the experiments now in progress in the Arkansas Valley give indications of like character.

Mr. Chairman, I have prepared a statement in relation to the artesian wells of the Great Plains which is partly in tabular form, with a brief explanation of the geologic conditions under which these artesian formations exist. With your permission I will present it.

GEOLOGICAL DATA RELATING TO ARTESIAN WELLS IN THE SUBHUMID REGION OF THE GREAT PLAINS.

THE DAKOTAS.

Location.—The artesian wells in the Dakotas are situated east of the one hundred and first meridian, and, with the exception of the one at Pierre, they are east of the one hundredth meridian. They occur in great numbers in the Red River Valley, making a belt through the Dakotas, with adjacent portions of Minnesota and Manitoba, and making a second nearly parallel belt running from Yankton northward to Devil's Lake.

Classification and reference to geological horizons.—The successful wells thus far bored in the Dakotas and adjacent regions, may be arranged in four groups, with reference to the geological horizons from which they derive their water supply. These are, (1) wells of little depth which do not pass through the drift; numerous in the Red River Valley; (2) those which penetrate to the Cambrian rocks, as at Grafton, N. Dak.; (3) those deriving their water supply from the middle or upper portion of the Cretaceous, illustrated by a single well in the western part of Cass County, and by several wells in the Red River Valley which pass through the drift; (4) those penetrating to the Dakota sandstone, the basal member of the Cretaceous. This group is important, and is illustrated by numerous wells ranging from Vermillion and Yankton northward to Devil's Lake.

Wells in the region adjacent to the Dakotas.—Artesian wells have been bored in the States and Territories bordering the Dakotas on the east, north, and west, a knowledge of which is valuable in discussing the possibilities of the subterranean water supply in those States themselves. The favorable conditions for supplying water in the Red River Valley extend northward into Canada, as far, at least, as Winnipeg, and eastward into Minnesota.

The successful wells in Manitoba, with the exception of one at Rosenfeld, about 20 miles northwest from Emerson and St. Vincent, are all in superficial deposits. The well forming the exception has a depth of 1,037 feet, and penetrates to the Cambrian. The water flowing from it is saline.

The shallow wells of Manitoba are as follows:

Location.	Depth.	Strata penetrated.	Water supply.
	Feet.		
Near Letellier	250	Drift (150 feet?) and Cretaceous or Silurian.	Saline and alkaline.
12 Manitoba Wells of Morris	250	.....do.	Do.
Dominion City	107	Drift till under lacustrine and alluvial beds.	Brackish.
Near Niverville (about twenty wells).	40-170	Drift, nearly all till	Good, fresh water.
Winnipeg (several wells)	50-100	......do.	Do.

The successful wells of eastern Minnesota which penetrate strata below the drift are as follows:

Location.	Depth.	Strata penetrated.	Water supply.
Houston County:	*Feet.*		
Brownsville	590	Cambrian	
Wabasha County:			
Lake City	820	......do.	
Goodhue County:			
Red Wing	450	......do.	
Dakota County:			
Hastings	1,160	......do.	
Mendota	857	......do.	Fresh, rising 10 feet above surface.
Freeborn County:			
Albert Lea	300	Devonian	
Blue Earth County:			
Minneopa Falls	1,000	Cambrian	
Nicollet County:			
Saint Peter	200	......do.	
Hennepin County:			
Minneapolis	205	Lower Silurian and Cambrian, *i. e.*, Trenton and St. Peter sandstone.	Fresh, abundant.
St Louis County:			
Tower	400	Archean schists	Do.
Traverse County:			
Brown's Valley	465	Cretaceous (Fort Benton shale), to Dakota sandstone.	Saline and alkaline.
Kittson County:			
Humboldt	644	Cambrian	Do.

The unsuccessful wells of eastern Minnesota are as follows:

Location.	Depth.	Strata penetrated.	Water supply.
	Feet.		
Mankato	2,204	Cambrian	Rose to 90 feet below surface.
Minneapolis	622	Trenton and Cambrian	
Do	1,431	......do	
Do	2,150	......do	
St. Paul	671	......do	
Do	850	......do	
Freeborn	950	Devonian	
Stillwater	3,500	Through Potsdam into Keweenawan	
Duluth	1,507	Archean	
Tracy	724	Through Cretaceous to granite	
Moorhead	1,425	Drift, 220; Cretaceous, 150; Archean, 1,055.	

The wells of Minnesota which are successful but do not penetrate below the drift are as follows:

Location.	Depth.	Strata penetrated.	Water supply.
Blue Earth and Faribault Counties:	*Feet.*		
Sterling, Mapleton, Wells, etc. (about two hundred wells in the vicinity of Maple River, on the area of the Glacial Lake Minnesota).	25-120	Till, with included seams of water-bearing sand and gravel.	Fresh, copious.
Douglas County:			
Osakis	60	do	Fresh, scanty.
Hudson	35	Glacial drift (till) with included seams of water-bearing sand and gravel.	Do.
The following are in the Red River Valley, on the area of the Glacial Lake Agassiz:			
Traverse County:			
Near Wheaton	119-182	do	Fresh, abundant.
Tintah	55	do	Do.
Do	45	do	Do.
Do	67	do	Do.
Near Tintah	35-160	do	Do.
Wilkin County:			
Champion Township, many wells.	50-66	do	Fresh, very copious.
Atherton	11	do	Fresh.
Do	37	do	Do.
Do	45	do	Do.
Clay County:			
Near Barnesville	35	All these go through thin lacustrine and alluvial beds, then are for most of their depth glacial drift (till), with seams of water-bearing sand and gravel.	All fresh, with copious supply.
Near Sabin	180		
Near Moorhead	100-228		
Kragnes	155		
Near Georgetown	180		
Becker County:			
Hamden	75		
Do	110		
Norman County:			
Perley	200		
Halstead	250		
Eight miles northeast of Halstead	165		
Do	219		
Ada	217		
Lockhart	140		
Lockhart vicinity	125-150		
From Ada to Crookston many wells	100-200		
Polk County:			
Near Kittson	80-112		
Do	140		
Carman	190		
Near Crookston	180		
Do	190	Alluvium and lacustrine beds, then glacial drift (till), in which are water-bearing seams of sand and gravel	Fresh, copious.
Do	205	do	Do.
Do	236	do	Do.
Vicinity of Crookston, probably one hundred wells.	165-240	do	Do.
Fisher	285	do	Alkaline and saline, copious.
Near Angus	45	do	
Do	70	do	
South Angus	253	do	Do.
Marshall County:			
Argyle	150	do	Do.
Do	285	do	Do.
Tamarack and vicinity.	74	do	Do.
Do	93	do	Do.
Do	218	do	Do.
Stephen	220	do	Do.
Do	240	do	Do.
Kittson County:			
Donaldson	45	do	Do.
Near Kennedy	95	do	Do.
Near Hallock	119	do	Fresh, copious.
Near Northcote	30	do	Do.
St. Vincent	165	do	Saline, copious.

West of the Dakotas wells have been bored in search of artesian water at the following localities:

Location.	Depth.	Strata penetrating.	Water supply.
	Feet.		
Glendive		Laramie or Fox Hills	
Miles City (fourteen wells)	180–550	Laramie (?)	
Billings	1,000		Not flowing.
Bozeman			
Helena	160	River gravels	200 gallons per minute.

Wells in the Dakotas.—The deep wells of the Dakotas, with exceptions noted later, are situated in a belt ranging from Vermillion and Yankton northward to Devil's Lake, and derive their water from the Dakota sandstone. The available data concerning these is given in the following table:

Locality.	Depth.	No. of wells.	Diameter of bore.	Temperature.	Pressure (per square inch).	Elevation (surface above sea).	Surface of Dakota (above sea).
	Feet.		*Inches.*	*° Fah.*	*Pounds.*	*Feet.*	*Feet.*
Vermillion	350					1,150	
Yankton	610	15	6	62	32	1,196	616
Do	165				140	1,196	
Yankton vicinity		15				1,196	
Tyndall	600				122	1,418	
Mitchell	1,300					1,301	
Plankinton	1,500				140	1,528	
Kimball	1,100				95	1,788	
Chamberlain						1,363

One hundred gallons per minute will give 4 inches of water to 119.3 acres in three months.

The wells enumerated above derive their water from the Dakota sandstone. Those at Vermillion and Yankton were begun in the Fort Benton. The remainder were begun in the Fort Pierre and pass through the Fort Benton.

Chemical composition.—The water in the wells indicated in the above table is generally brackish or alkaline, not therefore adapted for drinking or culinary purposes, and objectionable for use in steam boilers on account of the mineral salts deposited from it.

The water in the artesian well at Jamestown has been analyzed with the following result:

[Hardness, 21 degrees.]

	Parts per million.	Grains in U.S. gallon.
Test for organic matter:		
Free ammonia	2.4	...
Albuminoid ammonia	.046	...
Permanganate test:		
Oxygen consumed by carbonaceous oxygenic matter in three hours	6.7	...
Nitrates	None.	...

Carbonate of lime	188.0	.1283
Sulphate of lime	249.0	10.6743
Sulphate of magnesia	154.2	14.5241
Sulphate of soda	1139.4	8.9044
Sulphate of potash	81.5	66.3602
Chloride of sodium	369.1	4.7523
Phosphates	Trace	21.5296
	2222.6	129.2496

Professor Dodge, the chemist who made the analysis, states that in his opinion this water would not be suitable for regular use as a drinking water.

A qualitative analysis of the water in the well at Devil's Lake has also been made by Professor Dodge, which shows that it is of about the same composition as the water in the Jamestown well.

The following notes from report of Irrigation Committee, Vol. I, 1883, in reference to the water from other wells of the same class as those just mentioned, is here inserted:

Yankton.—Water slightly hard; pleasant to the taste; is used in boilers and gives good satisfaction.

Highmore.—Water very soft and of good quality.

Miller.—Water excellent and good for all purposes.

Ipswich.—Water very soft; contains soda, potassium and allied salts; tastes slightly brackish.

Columbia.—Water contains mineral properties; very soft.

Ellendale.—Water not pleasant to the taste; very soft.

These analyses and notes indicate that the water derived from the Dakota sandstone does not contain sufficient alkaline salts to be injurious to vegetation, especially in a region that has a rain-fall as great as that of the eastern part of the Dakotas.

In various portions of the testimony before the Irrigation Commission, the beneficial effects of irrigation with the water of Dakota sandstone wells are mentioned.

The temperature of the water derived from these wells in general increases with the depth of the boring. This is shown in the following table:

Well.	Depth.	Temperature.	Well.	Depth.	Temperature.
	Feet.	*°Fah.*		*Feet.*	*°Fah.*
Highmore	1,890	68	Columbia	1,304	60
Miller	1,587	80	Aberdeen	1,300	60
Ipswich	1,530	65	Ashton	1,296	55
Andover	1,476	64	Huron	1,285	60
Ellendale	1,453	65	Yankton	1,196	62
Jamestown	1,400	70			

Pleistocene wells.—The wells which do not penetrate below the drift are situated in the Red River Valley, principally in the bed of Lake Agassiz. The formation a few miles back from the river is glacial till, nearer the river the till is overlain by lacustral salt. Fresh water is obtained from the wells south of Blanchford, N. Dak., and Crookston, Minn. Farther north their waters are almost invariably brackish and alkaline, and not suitable for household use or drinking, although they are liked by cattle and horses, and are not injurious for this purpose.

The wells in the Red River Valley number more than one thousand. Of these about one-half are in North Dakota. They range in temperature from 46° to 50° Fah. in the south, to 42° Fah. at the north. The available data concerning a few of those in North Dakota is here inserted:

Location.	Depth.	Strata penetrated.	Water supply.
	Feet.		
Richland County:			
Farmington	93	Thin alluvial and lacustrine beds; then the principal thickness consists of glacial drift (till), in which are water-bearing seams of sand and gravel.	Fresh, copious.

Grand Forks	265		
Do	270		
Manvel	166		
Do	175	Thin alluvial and lacustrine beds; below these a great thickness of glacial drift (till), in which are water-bearing seams of sand and gravel.	All in this northern part of the valley are brackish and alkaline.
Walsh County:			
Ardoch	164		
Minto	196		
Do	200		
Grafton	156		
Auburn	175		
Pembina County:			
St. Thomas	175		
Glasston	200		
Hamilton	179		
Bathgate	143		
Bathgate, vicinity (eleven wells)	130-160		
Neche, vicinity	220		

The wells not included in the classes already noted are as follows:

Location.	Depth.	Strata penetrated.	Water supply per minute.
	Feet.		*Gallons.*
Grafton	915	Passed through stratified rocks to granite.	1,000.
Tower City	670	Fort Pierre shales to Niobrara horizon.	9½; rises 33 feet.
Casselton and vicinity	317-350	Passed through the drift into cretaceous rocks.	Brackish alkaline, copious.
Amenia and vicinity	250-279	do	Do.
Blanchard and vicinity (six wells)	300	do	Do.
Mayville	395	do	Do.

All of the wells enumerated in the last table, excepting the one at Tower City, are situated in the Red River Valley, and passing through the glacial drift enter older formations.

The one at Grafton passes through the Cambrian and into the granites beneath. Water was first reached at the depth of 503 feet; 400 feet deeper and resting on granite, a second sandstone stratum was reached which contained saline water. The well was continued 12 feet into the granite, but was subsequently filled so as to receive water only from the first water-bearing strata reached.

The remainder of the wells in the Red River Valley which pass through the drift are supposed to derive their supply from the middle portion of the Cretaceous.

Sources of water supply.—The source of the water in the wells which do not pass through the drift, although indefinite and perhaps impossible to determine accurately, owing to the irregular stratification of the deposit, is certainly not distant, and depends on the rain-fall and topographic configuration of the immediate region. It is possible, however, that the salt wells in this region may be supplied from springs in older rocks which are deeply drift-covered. The principles applicable to continuous water-bearing strata included between impervious beds and conducting water from distant sources, can not be applied to wells of this class.

The wells which derive their supply from the Fort Pierre, Fort Benton, Dakota, and Cambrian formations, on the other hand, penetrate evenly bedded strata, and depend for their supply on the hydrostatic pressure of water derived from distant sources.

In order to determine the source of the water in these wells, one must ascertain where the water-bearing strata out-crop at an elevation sufficient to insure a flow at the surface where the wells are situated.

The Cambrian and Silurian rocks underlying the eastern portion of the Dakotas come to the surface in Minnesota and adjacent portions of Canada. It is barely possible, as I have been informed by C. R. Van Hise, that these strata may derive their water from the eastern outcrops indicated. A general western inclination of these rocks from their outcrops west and north of Lake Superior seems probable from what is known concerning them, but the data in hand are not sufficient to warrant positive conclusions.

The eastern outcrop of the Cretaceous system coincides in North Dakota with the eastern escarpments of the Coteau des Prairies along the western border of the Red River Valley. Its western outcrop is along the eastern bases of the various front ranges of the Rocky Mountains and about the Black Hills.

The elevation of the region in which the wells penetrate the Dakota sandstone in the eastern part of the Dakotas is from 1,000 to 1,900 feet above the sea. The water comes to the surface under a pressure of from 15 to 187 pounds per square inch. The maximum is at Groton, the altitude of which is 1,300 feet above the sea. The pressure in this well is sufficient to raise the water 432 feet, and even if the loss of pressure by friction is not considered it is evident that the source of the supply must have an altitude of at least 1,700 feet above the sea. The pressure in other wells in the same series indicates a source of supply at an elevation of 1,950 feet. It is known from railroad surveys and other sources that there is no land to the south, east, or north of Groton at a sufficient elevation to furnish water under the pressure given, even if the water-bearing strata outcrop at the surface under the most favorable conditions. The eastern outcrop of the Dakota sandstone in South Dakota and the adjacent portion of Nebraska has a maximum elevation of about 1,500 feet. It seems evident, therefore, that we must look to the west for the fountain-head of the wells which reach the Dakota sandstone. The nearest outcrop of that formation at the west is about the Black Hills at an elevation of approximately 3,300 feet above the sea. It comes to the surface again still farther west, about the eastern base of Big Horn Mountains, at an elevation of about 4,500 feet.

The general inclination of the Dakota sandstone and of the strata which rest upon it is known to be eastward from the eastern base of the Rocky Mountains, although a secondary structure producing anticlinals probably exists. From what is known of the succession of strata in the eastern and western outcrop of the Cretaceous, and from the suggestion furnished by the high pressure of the water derived from the lower member of the series in eastern Dakota, it seems exceedingly probable that the Dakota sandstone forms a continuous stratum beneath the Great Plains. If the water obtained from this stratum is derived from the Rocky Mountain region as indicated by our present knowledge, it follows that success might be expected if wells were bored in the region between the Red River Valley and the eastern basin of the Rocky Mountains.

The thickness of the Dakota sandstone as given by F. V. Hayden at its outcrop about the Black Hills is 400 feet. At Lincoln, Nebr., as stated by Professor Hicks, it is 204 feet. Along its outcrops it is a porous sandstone sometimes passing into a conglomerate, and where it has been penetrated by borings in the Dakotas it is very friable and open in structure. Its thickness, porosity, and extent, as well as its attitude, so far as is known are all in favor of its being an abundant source of artesian water.

Thickness of strata above the Dakota sandstone.—The formations which occur in the general region under discussion, as given by F. V. Hayden, are as follows:

Name.	Character of strata.	Thickness.
		Feet.
Loup River beds	Fine loose sand, with some layers of limestone	300-400
White River group	White and light drab clays, with some cavities of sandstone and local layers of limestone.	1,000
Wind River deposits	Exposed principally in Nebraska	1,500-2,000
"Fort Union," Laramie	Sandstone with shale	2,000-10,000
Fox Hill	Gray ferruginous and yellow sandstone and arenaceous clays.	500
Fort Pierre	Dark gray plastic clays above; dark beds of very fine unctuous clay, containing much carbonaceous matter with veins and seams of gypsum, etc., below.	700
Niobrara	Lead gray calcareous marls above; light yellowish and whitish limestones below.	200
Fort Benton	Dark gray laminated clays, sometimes alternating near the upper part with layers of light gray limestone.	800
Dakota	Yellowish, reddish, and occasionally white sandstone, with alternations of various colored clays and beds of lignite.	400

The surface throughout the region occupied by the Dakotas has been greatly eroded and it is not probable that the entire series as given above anywhere exists. It is to be expected also that the strata above the Dakota sandstone may be found of variable thickness and lithological character. These considerations as well as the secondary structure of the Great Plains would have to be investigated in order to predict for any locality at what depth the water-boring strata might be reached. Some of the wells in eastern Dakota derive their water supply from middle Cretaceous. The conditions to the west of where these wells are located seem equally favorable for obtaining flowing water from this horizon. It is to be expected, however, that water derived from these strata would be less pure than from the Dakota sandstone and consequently of doubtful value for irrigation. The Laramie may also be expected to yield artesian water.

Beneath the Dakota along the western outcrops there are shales and other impervious strata belonging to the Triassic system. It is to be expected that these coarse Triassic beds will carry water, but the great depth at which they occur underneath the Great Plains probably renders their consideration as a source of water supply necessary; besides, the Triassic strata are so highly charged with easily soluble salts that water derived from them would be too alkaline and saline for irrigation or domestic use.

NEBRASKA.

The geological formations of this State comprise the Upper Coal Measures, and possible Permian; the Cretaceous, but including only the Dakota, Fort Benton, Niobrara, and Fort Pierre, and the White River Tertiary of Hayden.

Lithological composition.—The component beds of the Coal Measures are shales, limestones, and sandstones, in alternating bands; the limestones of greater or less thickness form a prominent feature of the outcrops along the Missouri and in the numerous railroad and water cuts leading to this river.

The Cretaceous formations present the following composition: The Dakota, from 300 to 400 feet of a soft, loose textured, white sandstone, separated by narrow beds of shale into bands of from 50 to 80 feet; its width of outcrop in Nebraska is about 60 miles. The Fort Benton, a series of dark black or bluish gray, compact, argillaceous, shales, with a few narrow limestone bands; in thickness between 300 and 800 feet, but probably nearer the former figure in Nebraska. The Niobrara, between 200 and 400 feet in thickness, composed of shales and limestones, the latter a most prominent feature of the formation, and in Dakota, Nebraska, and Kansas of a decidedly chalky nature rather than that of a massive, hard limestone, as along the foot-hills of the Rocky Mountains. The Fort Pierre, essentially a formation of light gray, plastic, clay shales, of variable thickness in Nebraska, owing to its deposition in undulations of the Niobrara below, and to erosion from its summit prior to the laying down of the White River Tertiary above.

The White River Tertiary is a formation of sandstones, conglomerates, and interbedded shales. It is the surface formation of western Nebraska and southwestern Dakota, where it rarely shows a thickness of over 400 or 500 feet.

Areal distribution.—The areal lines of division between the Tertiary, Cretaceous, and Carboniferous ages are clearly defined. That between the Cretaceous and Coal Measures, which also constitute the eastern limit of the Dakota formation in Nebraska, crosses the Missouri River a short distance below Dakota City, follows down the west side of the river a few miles inward from its bluffs to a point on the Platte about 8 miles above its mouth, when it inclines to the southwestward, passes through Cass, Otoe, Johnson, and Gage Counties, and joins the eastern boundary assigned the formation in Marshall County, Kans. The line of division between the Cretaceous and Tertiary crosses the northern boundary of the State in longitude 100, the southern in 99, and within these limits has a broad convexity to the east, crossing the Platte a little to the east of the ninety-eighth meridian; with the exception of a small area of erosion on the upper Republican, in which the Pierre shales are exposed, the entire State west of this line is occupied superficially by the White River Miocene.

Non-conformities exist both above and below the Cretaceous, the Dakota resting in uneven line upon the Coal Measures or Permian, the White River upon the greatly eroded surface of the Pierre; furthermore, here as elsewhere there also exists abundant evidence of a prominent break in the continuity of deposition between the Niobrara and Fort Pierre formations, within the Cretaceous itself.

Geological structure.—The geological structure of Nebraska is that of gently inclined strata, having a general dip to the eastward somewhat less than the slope of the surface, with a slight "basining up" of the formations in the eastern part of the State, the dip there being to the northwest in continuation of that of the corresponding beds in Dakota and Kansas.

The following altitudes in Nebraska, which are of use in connection with the geological structure, are from Aughey's "Physical Geography and Geology of Nebraska" and Gannett's "Dictionary of Altitudes in the United States."

Locality.	Altitude.	Remarks.
	Feet.	
Scott's Bluffs, on State line	6,051	Northern line of State.
Niobrara River, southeast of Fort Robinson	4,118	
Indian Creek, northwest corner of State	4,013	
Fort Robinson, 103° 30′ meridian	3,781	
Mouth of Snake River, one hundred and first meridian	2,690	
Mouth of Keya Paha, ninety-ninth meridian	1,960	
Niobrara, ninety-eighth meridian	1,240	
Pine Bluffs, one hundred and fourth meridian	5,061	In the southern half of State.
Sidney, one hundred and third meridian	4,095	
Ogallala, one hundred and second meridian	3,216	
Kearney, ninety-ninth meridian	2,157	
Average of five, on ninety-seventh meridian	1,203	Northern to southern boundary.

Central City, the lowest point on the eastern line of the Tertiary, has an altitude of 1,708 feet. The eastern boundary of the Cretaceous will lie between 1,000 and 1,200 feet, a fall of at least 3,000 feet from the western line of the State.

Artesian wells.—Nebraska has apparently been but slightly explored with reference to the possibility of artesian wells. Record has been found of but four, one at St. Helena, a short distance below Yankton; one at Omaha; one at Lincoln, a mineral water; and one at Brownville, in Nemaha County, in the southeastern part of the State.

That at St. Helena derives its waters from the Dakota sandstones, at a depth of 400 feet, and in reality belongs to the system of South Dakota. The flow is copious.

The wells at Omaha, 750 feet, Lincoln, 985, and Brownville, 1,001 feet, derive their water from various strata in the Coal Measures. Of these the well at Omaha affords pure, fresh water. The Lincoln well yielded fresh water (not artesian) at a depth of 100 feet; a strong brine at 244 feet, the base of the Dakota, and medicinal water at 544 feet. The last is the water used. The flow is strong. Of the Brownville well no record of its water can be found.

From the above facts it is observed that the great water-bearing formation of the eastern part of the prairie region has been tapped at but one advantageous point in Nebraska, at St. Helena. Although the geological structure of Nebraska does not afford the confining beds of granite, quartzite, etc., to the easterm rim of the Dakota formation as it does in the Dakotas, nevertheless it is reasonable to presume from the success attending boring in the State of Kansas to the south, where the conditions are approximately the same as in Nebraska, that water may be obtained at numerous points over this belt; furthermore it is not impossible that the Tertiary beds themselves may afford flows at advantageous points within the area covered by them.

Tabular statement relating to the artesian wells of Nebraska.

Geological horizon.	Location.	Depth.	Delivery.	Remarks.
		Feet.		
Dakota	St. Helena, Cedar County	466	Copious	Pure.
Carboniferous	Omaha, Douglas County	750	Good	Do.
	Lincoln, Lancaster County	985	Copious	(1) Brine from 244′ (Dakota), cased off. Mineral from 544′ Carboniferous.
	Brownville, Nemaha County	1,001		(2) No other data
	Beatrice, Gage County	1,200		(3) No flow.

KANSAS.

The geological formations included within the area of Kansas comprise the Subcarboniferous, the Coal Measures, the Upper Carboniferous and Permian, the Trias, the Cretaceous, including, however, only the Dakota, Fort Benton, and Niobrara, and a Tertiary formation, probably Miocene.

Lithological composition.—The Subcarboniferous is recognized in the well-known Subcarboniferous limestone, and occurs only in the very southeastern corner of the State.

The Coal Measures, Upper Carboniferous, and Permian are an alternation of sandstones, limestones, and shales. In the Coal Measures the shales are often locally developed to great thickness; the limestones are very persistent, and the sandstones are rather subordinate. In the higher formations the sandstones become more prominent. The thickness of the Coal Measures is at least 1,000 feet, while the Permian and Upper Carboniferous comprise about 2,000 feet.

The Triassic shales, limestones, and "Red Beds" (shales with narrow sandstone bands), of a variable thickness up to 300 feet, succeed the Permian and Carboniferous rocks. It is probable that this formation is wanting in the northern portion of the State towards the Nebraska line.

The Dakota formation, as in Nebraska, is largely composed of sandstone, but with a somewhat greater development of shales; it varies in thickness between 300 and 500 feet.

The Fort Benton ranges in thickness from 50 to 260 feet—a wide variation—and in its component beds departs a little from the normal composition further north. According to Professor Mudge its upper 60 feet is a bed of limestone, in layers from 1 to 3 feet thick, underlain by 60 feet of bluish-black shale abounding in concretions of a calcareous nature, this series underlain in turn by 140 feet more of shales, somewhat variable in composition and with several narrow bands of limestone distributed through them.

The Niobrara is of nearly its usual character, but is rather more chalky in appearance. Its thickness in Kansas varies from 75 to 200 feet.

The maximum thickness of the Cretaceous in Kansas is estimated by Professor Mudge to be about 900 feet. The basal member, the Dakota, rests unconformably upon the Carboniferous below.

The Tertiary of Kansas consists of cemented coarse-grits and sandstones. Its age is regarded by Robert Hay as Miocene. It is everywhere unconformable with the Cretaceous.

Areal distribution.—The areas covered by the several formations of Kansas are: for the Trias, Permian, and Carboniferous the southeastern third of the State; for the Cretaceous, a broad median belt lying in a northeast-southwest direction; for the Tertiary, the northwestern fifth of the State, together with a small extension from Colorado into its southwestern corner.

The line of division between the Cretaceous (Dakota) and the formations below starts at the Nebraska line, in Marshall County, follows a somewhat irregular line through Washington, Clay, Dickinson, Morris, Marion, McPherson, Rice, Reno, Pratt, Comanche, and Clarke Counties, where it crosses the southern boundary of the State. Its western boundary, or the line between it and the Tertiary, starts in Jewell or Phillips Counties, and passes with irregular trend west-southwestward, leaving the western boundary of the State a short distance north of the Arkansas River.

Of the Cretaceous formations the Dakota occupies a belt along the eastern border of about 50 miles' width, the remainder being occupied by the Fort Benton and Niobrara, but largely by the latter.

The geological structure.—Although both the Carboniferous beds and the eastern half of the Cretaceous exposures have a gentle dip to the westward, there is nevertheless a general rise of the beds to the westward, especially well brought out in the Cretaceous series itself by the exposure of its several members along the western border of the State. This rise, so far as the Cretaceous is concerned, amounts, according to O. St. John, to from 1,100 to 1,700 feet, the altitude of its exposures in Hamilton County being in the vicinity of 3,150. There is, therefore, as in Nebraska, a general eastward fall of the water-bearing beds, with a in slight though pronounced "basining up" to the eastward, with the axis in the region of Larned, extending northeast and southwest.

Artesian wells.—The artesian wells of Kansas derive their waters from four different formations: The Miocene, Dakota, Trias, and Carboniferous. Of these the Miocene wells—with two possible exceptions in Norton and Sheridan Counties in the northwestern part of the State—are at present confined to Meade County on its southern boundary; the Trias wells occur, one at Richfield in Morton County, and one at Larned in Pawnee; the Carboniferous, one at Russell, Russell County, and one at Winfield, Cowley County, while the remaining or Dakota wells are distributed over the Cretaceous belt from near the Nebraska line to that of the Indian Territory.

The Miocene wells of southwestern Kansas have their source in the Miocene grits and sandstones already mentioned as present in this portion of the State. These coarse, arenaceous, and pebbly beds are covered by a soft, bluish, putty-like clay or gumbo, which forms the subsoil of the region, is thoroughly impervious, and is the effective confining stratum for the waters beneath. The gravelly beds receive their waters at their outcrops in the very western part of the State and in Colorado into which they extend. The wells number about sixty or seventy and vary in depth from 50 to 185 feet. A number of them flow from 18 to 36 gallons per minute, and a still greater number flow only from 1 to 6 gallons. None of them are strong wells, though the water of some of the lower ones will rise from 15 to 20 feet above the surface. Concerning the wells in Norton and Sheridan Counties nothing of detail is known.

The wells of the Trias, at Richfield and Larned, derive their waters respectively from depths of 570 and 750 feet. The Richfield well yields 6.3 gallons per minute, but is somewhat mineralized. The Larned well flows over 250 gallons per minute, and rises as a fountain between 10 and 15 feet. Its waters are a strong brine with medicinal properties.

Of the Carboniferous wells, that at Russell is 977 feet deep, the one at Winfield 1,200 feet; both have good flows, but are strongly saline.

The Cretaceous wells of Hamilton County are the only ones of which detailed data exist. They are numerous, range from 200 to 300 feet in depth, and flow from 45 to 100 gallons per minute. Some of them are used for irrigation purposes. The well at Great Bend is 1,400 feet deep, but receives its waters, which are saline, from the Dakota sandstone at a depth of 344 feet. It has a strong flow, which rises 30 feet above the surface.

From the geological structure of Kansas and the results of borings in other States it is quite possible that the Coal Measures may be found productive of artesian waters whenever attempts with this special object in view shall be made.

TEXAS.

The geological formations of Texas involved in the areas of artesian wells include the Coal Measures, the Cretaceous, and the Tertiary.

Lithological composition.—The Coal Measures consist principally of limestone, sandstone, millstone-grit, and shale. The limestones and sandstones exist in about equal proportions and constitute the chief part of the formation. The sandstone is both massive and thin bedded, is fine grained or course, passes into grit, or conglomerate, and exhibits every degree of hardness. It is interbedded with shales in successive strata reaching 100 feet in thickness.

The Cretaceous of Texas differs considerably from that at the north. According to Shumard it consists of an upper and lower member. The former consists of limestone and sandstone, in southern Texas the limestone predominating, but being largely replaced by sandstone in northern Texas, the limestone here occurring in thin bands separating the heavier beds of sandstones.

The Lower Cretaceous is composed chiefly of marly clays with some limestone, sandstone, and gypsum. The clays and sandstones occur in alternating beds of variable thickness. The sandstone is fine-grained to coarse, thinly laminated, is often calcareous, and usually quite soft.

Both Upper and Lower Cretaceous vary greatly in thickness, the former reaching a maximum of 1,000 feet on the San Pedro River, the latter 2,500 on the upper Red River.

The Tertiary formation to be considered in this connection occurs as a bed of soft, white sandstone 200 feet thick, known as the Carrizo sandstone. It rests unconformably on the Cretaceous, as does the Cretaceous upon the Coal Measures.

Areal distribution.—The Coal Measures, not less than 2,000 feet thick, are confined to the northern half of the State. They are overlaid by a narrow belt of Permian on their west, the area of the two being inclosed on the east, south, and west sides by the various strata of the Cretaceous, chiefly those of the lower division. The western boundary of the Permo-Carboniferous formation passes through Baylor, Throckmorton, Jones, Taylor, Runnells, Concho, and Menard Counties, the eastern through Montague, Palo, Pinto, and Lampasas Counties.

The Cretaceous series as a whole is of wide extent, the portion west of the Carboniferous area reaching far beyond the western boundary of the State into New Mexico. The prevailing dip of the Cretaceous and Carboniferous formations from near the eastern edge of the latter westward is to the northwest; east of this point it is to the eastward.

The extent of the Carrizo sandstone is at present unknown. Its western boundary has been traced for a distance of about 100 miles, from near the town of Uvalde, southward to the Rio Grande River. Its dip is to the southeastward.

Artesian wells.—The artesian wells of Texas derive their waters from the sandstones of the Coal Measures, from those of the Cretaceous, and from the Carrizo sandstone of the Tertiary.

Of the depth or flow of the wells within the limit of the Coal Measures nothing is at present known, but it is probably somewhat variable from the very nature of their component strata.

Of the depth or flow of the greater number of the Cretaceous wells likewise nothing is known. In the southern part of the State, however, existing data enable the following statement:

The wells of San Antonio, two in number, 225 feet and 450 feet in depth, probably both derive their waters from the lower portion of the Cretaceous, though it is possible the deeper one, to the east of the city, may find its supply in the Coal Measures. The former of the two wells affords an excellent drinking water and has a steady, though not strong, flow; the latter has also a steady flow, stronger than that of the shallower well, and its waters, although used for ordinary drinking purposes, have medicinal properties that may render them of special value in the future.

The Cotulla well, 1,008 feet deep, is also probably of lower Cretaceous origin, though it may extend a short distance into the Carboniferous; its waters have a strong flow and are of superior medicinal properties.

In the northern portion of the State, the wells of Fort Worth and Dallas derive their waters from the basal sandstones of the Cretaceous, at a depth of 350 and 750 feet, respectively. The dip is to the eastward. In this section the upper confining stratum is apparently the limestones of the chalk formation (Niobrara ?).

The Tertiary well at Carrizo Springs penetrates the Carrizo sandstone to a depth of 175 feet, and has an excellent flow of fresh water four inches in diameter.

Tabular statement relating to the artesian wells of Texas.

No.	Geological horizon.	Location.	Depth.	Caliber.	Delivery.	Remarks.

In the hasty review which has thus been made of the various drainage basins of the arid region, I have pointed out that there are a number of international questions involved in the use of the rivers for irrigation. One of these questions you have already had presented to you, namely, that of the Rio Grande Del Norte, where the rights of the people of the Republic of Mexico as well as the rights of the people of Texas are threatened and almost destroyed by the people of Colorado and New Mexico. Already claim has been made for more than $1,000,000 by the people of the lower country to re-imburse them for their lost values, or to restore to them by some means the volume of water necessary to carry on their long-established industries of agriculture. Ultimately the problem on the Colorado will be of far greater magnitude. The Colorado itself can be used in our territory, or in Mexican territory, and can be made to irrigate in one or the other country, or in both, many millions of acres. Above, it is in the United States; below, it is in Mexico. Who shall divide the waters between the two nations? On our northern boundary line similar questions are asked. The Columbia and some of its tributaries, some of the tributaries of the Missouri, and others of the Saskatchewan running northward, cross the boundary line, so that their waters must be divided between the two nations. Altogether the problem of the utilization of the rivers for irrigation in the western half of the United States presents international questions, that must ultimately be settled, far exceeding in importance and in values those that relate to fisheries, or any other international subject affecting the industries of the country. In some localities the questions press for solution now; in others they will arise in the immediate future, and must be solved if peace is maintained.

The international problems sink into insignificance in comparison with the interstate problems. Every great river and every great tributary of the entire arid region and of the subhumid region, or more than one-half of the area of the United States, exclusive of Alaska, runs through two or more States and Territories. In a few cases they are boundary lines, in others they head in one political division and run through another. In all these cases the waters must be divided on some equitable and wise principle. In general the headwater States and Territories have it in their power to control the situation. They can take the water and laugh at the rights of the people lower down the rivers. The North Platte is to be divided between Wyoming and Nebraska; the South Platte between Colorado and Nebraska; the Arkansas between Colorado and Kansas; the Canadian River between New Mexico and the Indian Territory; the Pecos between New Mexico and Texas; the Rio Grande del Norte between Colorado, New Mexico, Texas, and the Republic of Mexico; the Colorado between Wyoming, Utah, Colorado, Arizona, Nevada, and California.

All the principal rivers of Nevada head in California. The Bear River is to be divided between Wyoming, Idaho, and Utah; the Snake is to be divided between Wyoming, Idaho, Oregon, and Washington; the Columbia is to be divided between Montana, British America, and Washington; the Missouri and its tributaries are to be divided between Montana, North Dakota, South Dakota, and perhaps Nebraska. In this enumeration I have only taken up the more important streams and have omitted many minor ones that involve severally great interests. Many of these in single cases will involve values of one to five millions of dollars. It is safe to say that the distribution of industries between the States through a division of the waters to be used in irrigation involves industries now established or to be developed of not less than

$1,000,000,000. These problems are already pending in many places to the extent of many millions of dollars and they must all be solved in the immediate future if peace is to be maintained.

The history of interstate feuds in the United States relating to the boundary lines and fishing interests in dividing waters is replete with lessons showing that even such small interests kindle animosities and create difficulties of serious importance. Shall State arm against State over disputed questions relating to the use of water? Will it not be an act of wisdom to settle these disputes in their incipiency before the passions of the people are inflamed and before rights and interests are established. If neglected it will result in the establishment of agricultural industries in various regions that must inevitably be destroyed.

The development of these industries, the growth of vast interests, is now in progress, and the people in many districts are already piling up claims against the Government of the United States which will ultimately amount to vast sums; and if it shall continue for twenty years more as it has progressed for the past five years, claims against the Government will be pressed involving many hundreds of millions of dollars; and if such claims are rejected, hundreds of thousands of people will have their industries destroyed, and will be left in abject poverty to abandon their homes and fields and to migrate to new regions.

Again, if the development of the country is to go on in the present method without regulation and without prevision, agriculture will largely be driven to the mountains, about the sources of the great rivers which ought to be used in the valleys below. If, on the other hand, the right to take out the waters above is overthrown, through the courts and through legislation, and the right to the flow of the stream at the lowest points in the valley where irrigation is necessary is established, the waste of water will be enormous, and not one-fifth, and perhaps not one-tenth, of the possible area of agriculture will be realized. For the ultimate prosperity of the agriculture of those lands, and for the avoidance of conflict, it is necessary that the waters of the entire arid region be divided and relegated by drainage districts to the best lands, in such a manner that the people of each district will know what lands can ultimately be irrigated and what waters can ultimately be utilized; and it is possible by some simple measures of prevision to anticipate nearly all of the difficulties which I have pointed out, in so brief and imperfect a manner, and have them all solved in advance of dense settlement. I have already alluded to the improvident and obstructive rights which are being established along the course of many streams—rights which must ultimately be extinguished, and some of which are now in process of extinguishment. A proper administration of this trust, this heritage of wealth and homes for the people, may be devised. Millions of wealth of this nature may be created which must necessarily be extinguished in the near future. Is it wise to permit its creation?

There is still one other very important class of facts which must be mentioned. The reservoir and canal sites should remain in public possession, in trust for the people who will need them. The statutes already provide for their discovery, segregation, and reservation, but some provision must be made for their utilization. It is manifestly not the purpose to reserve them from use, but to reserve them for use, and to prevent them from falling into the hands of individuals or corporations for speculative purposes. But to whom shall they be turned over for use, and under what conditions shall their utilization be permitted, is the problem yet to be solved.

Equally important with the reservoir and canal sites are the sites for diverting dams along the courses of the streams. It is often the case, and perhaps generally the case, that the waters of a stream may be taken out at a particular place, and the entire volume controlled thereby, and the owner of such a site would have the command of all the agriculture dependent upon that stream. All reservoir sites and canal sites and diverting dam sites should be the property of the agriculturists and not of water companies. The waters themselves should be the property of the farmers and not of companies. If the water for agriculture is to be supplied by companies organized under national statutes or other charters they should be organized only as common carriers of water. It should be established that the land which is irrigated appropriates the waters, and that they are not appropriated by canals, but the water belongs to the farmer and not to the water company. And I believe still further that in the interest of peace and prosperity the farmers should not only own the waters and lands but they should also own the irrigating works.

Such are some of the more important institutional problems relating to the arid lands. The conditions of agriculture in the western half of the United States are unlike the conditions prevailing in the eastern half of the United States, and unlike the conditions of western Europe, from which our people came. The new conditions demand new institutions.

I have reviewed somewhat at length in the two examinations which you have given me the principal problems involved in the arid lands. But I have presumed, and I wish to present it modestly, to formulate in the shape of a bill the ideas which I wanted to present, thinking I could do it in a more systematic and concise manner in that way. I think that this bill, if adopted or enacted into a law, would inaugurate a system that would solve the particular problems which I have indicated. Already some of the members of the committee have heard me talk on this subject. But I will give you an outline of the bill:

First, it is incumbent upon the Government of the United States to, and it is necessary that it should, divide the waters among the different States and Territories, from the fact that in twenty or thirty cases the problems are interstate problems, and in some of these cases the problems have arisen and the people are now in conflict. This conflict, too, is bitter. In other cases they involve only different districts within the same State or Territory. The theory of this bill is that the waters ought to be divided by the General Government.

Senator **MOODY**. Upon what principle of constitutional power do you attribute the authority of Congress to make these regulations and divide the water?

Director **POWELL**. I provide for it in my theory, not on a principle of law but on a principle of policy, and the last section of the bill provides that certain sections of the bill shall have no force nor effect until the State or Territory involved accepts it.

Senator **MOODY**. Congress would have the right to legislate for the Territories in those particulars undoubtedly. But the query was, what authority would Congress have to legislate upon such a subject for the States. Of course, if you take that theory, that the State will have to accept, that ends the matter.

Director **POWELL**. I have adopted that theory to meet that point.

I have also shown to the committee that all of the lands can not be irrigated, and that it is necessary to select the best.

I have presented to the committee a brief outline of the timber lands of the arid region, and have shown how the timber lands are being devastated by fire. There is before Congress a number of bills providing for a forestry organization by the General Government to protect these forests.

There is still another interest in these arid lands that I may mention before reading the provisions of the tentative bill.

In the area of the arid lands there are vast regions valuable only for pasturage. But if all the rivers, all the creeks, all the brooks and the springs, and all the artesian waters, and all the storm waters are utilized that we hope may be utilized in that country, there will still remain two classes of lands which will not be irrigated for agriculture. There will be large areas valuable for pasturage and valuable for the growth of timber. The timber lands are unfit for agricultural purposes. Waters, in the main, can be found there, but they are so high that agriculture is not profitable. Where timber grows frosts may be expected any month of the year. This tentative bill includes all the interests of that country—the pasture land and timber land, and provides a way for the use of that timber land and the use of that pasturage by the people, and provides further that only the irrigable lands shall be disposed of by the General Government.

If you will pardon me, I will read the bill through, first without comment, and then take up the various divisions and explain their purport and purposes.

(The proposed bill was then read to the committee.)

Director POWELL. Mr. Chairman, the theory of the bill is that there are natural hydrographic basins or drainage areas; that the people of each of these districts should be organized into bodies corporate and politic and constitute commonwealths for the regulation of irrigation, the division of waters, the protection of forests, and the protection of the pasturage lands, and for the utilization of all of these values.

The CHAIRMAN. How would you manage where there are vested rights and you want to get grants to give the districts power to institute proceedings for condemnation; where you want water rights; where you want to take out a ditch to cover land, and where you would have a conflict of water rights?

Director POWELL. I have concluded that that would be a matter for State regulation and not for the United States, and the bill provides that the States must enact the necessary laws. With the knowledge already at hand it is possible to outline most of the natural basins which are described as irrigation districts in this tentative bill. I place before you a map of the arid region outlining such natural districts. It also exhibits the county lines and the State lines, and shows how such districts would be relegated to counties and to States. Most of the districts embrace portions of two or more counties. The county lines, like the State lines, are artificial. In the main they follow parallels and meridians, as do the State lines, and hence usually do not coincide with the natural district lines. A number of districts embrace lands in two or more States or Territories.

The CHAIRMAN. How do you manage to give a district jurisdiction when it is partly in two States?

Director POWELL. I propose that the people of a district embraced in two States organize under United States laws and under State laws which are specified in the bill after the States and Territories have provided for such action, and by the consent and authority of the interested States and Territories.

Section 1 of the bill provides for the survey and designation of the irrigation districts, and three classes of districts are provided. They may be called head-water districts, river-trunk districts, and lost-river districts.

Section 2 provides that the irrigation survey shall select the irrigable lands, and to be governed in the process by the following rules: First, the conditions necessary to secure the greatest area of irrigable land; second, the conditions necessary to secure the most valuable lands for agricultural purposes by reason of climate; third, the conditions necessary to secure the most valuable agricultural lands as determined by soil and subsoil; fourth, the conditions necessary to secure lands that can be irrigated and cultivated with the greatest economy.

Section 3 provides that all lands heretofore irrigated in the arid region or for which irrigating works have been constructed, and all lands selected for irrigation by the Survey, shall be considered as irrigable lands.

Section 4 provides that the United States Survey shall designate the trunk sections of rivers and large creeks, and determine and locate the places on such trunk sections where dams may be constructed, and the routes to be followed in the construction of canals from such trunk sections, and that all shall be done in such a manner as to protect the water rights of the several districts and to prevent the construction of improvident and obstructive works of irrigation, and that it shall be unlawful to construct improvident and obstructive works.

Section 5 divides the waters among the irrigation districts, so that the people of each district will know definitely what waters they are entitled to.

Section 6 provides that whenever a source of water supply and the necessary irrigation works in any district lie within the boundaries of another State or Territory than that where the lands irrigated are situate, the people of the district shall have the right to construct and maintain their works in the State where they are situate, and that it shall be unlawful to levy any tax on or establish any obstruction to the use of such waters, sites, or works by the State or Territory in which they are situate.

Section 7 provides that the irrigable lands may be homesteaded in tracts of 80 acres. It re-affirms the laws relating to mining lands, coal lands, and town-site lands, and provides that all other lands shall remain in the possession of the General Government, to be used by them as catchment areas for the waters of irrigation, for the forests which they grow, and for the pasturage which they furnish, and that the sites of reservoirs and other irrigating works shall remain the property of the General Government, to be used by the people in their corporate capacity.

Section 8 affirms the right of every man who owns an acre of land to his portion of the waters set apart for the irrigable lands of his district.

Section 9 makes it unlawful for any person or corporation to construct irrigating works except in conformity with the statutes of the State or Territory and of the United States.

Section 10 provides a general form of organization for irrigation districts.

Section 11 relegates to the commissioners of each district the authority and duty to provide laws and rules for the use of the waters of the district in irrigation and for other purposes, for the protection and use of the timber and fire-wood of the district, and for the protection and use of the pasturage of the district.

Section 12 provides that such irrigation districts shall be organized under State or Territorial laws, and further provides four methods by which irrigation works may be constructed: First, by co-operative labor; second, by taxes levied on the lands irrigated; third, by the issuance of irrigation-district bonds; and fourth, by contract with companies. But when constructed by the last method, the irrigating works shall after a term of years become the property of the district. It also provides that the State or Territory may enact general laws for the protection and use of forests, and for the protection and use of pasturage.

Section 13 provides for State supervision of irrigation.

Section 14 provides that cities and towns may be excluded from the irrigation districts, and that the waters used for domestic purposes may be designated by State statutes.

Section 15, which is the last, provides for the general consent of the States and Territories involved.

It will thus be seen that the proposition is to organize irrigation districts with natural boundaries, and to relegate to each district the great body of the problems which are involved in this new industry of agriculture; and it divides the waters between the districts in a simple and effective manner. It also proposes that the irrigable lands shall be selected in the interest of all the people, that the greatest amount of agriculture may be carried on; and it provides for the protection and use of the forest and pasturage lands by the people who are interested therein. The vast increase in the value of lands by irrigation makes them an object of speculation. We are starting in a speculation in the West which I believe if unregulated by law, as it now is, with rights to waters undetermined, as they now are, will result in disaster to the farmers and the investors alike; and it will further result in this: that the water and the lands will go into the hands of a few persons, namely, the promoters of irrigating schemes. Be that as it may, the problem of fixing water rights somewhere, so that the farmer and the investor alike may be secure, remains, and is one of the serious problems that must be met; and I propose in the plan which I have presented that the Government of the United States interfere in the matter to the least possible extent; that it divide the waters—not to the farmers—but between districts and States, and then, under guarded provisions, turn over the whole subject to the States and districts and allow them to work out the matter to their satisfaction.

The committee here adjourned, to meet on Friday morning, the 24th inst., at 10 o'clock.

THIRD DAY'S SESSION.

WASHINGTON, D. C., *January* 24, 1890.

The committee met.

Present: Mr. Stewart, chairman; Mr. Plumb, Mr. Casey, Mr. Moody, Mr. Reagan, and Mr. Jones, of Arkansas.

STATEMENT OF DIRECTOR POWELL—Continued.

Mr. chairman and gentlemen of the committee, the work of the Irrigation Survey is naturally divided into three parts and organized into three branches, for there are three classes of work which are best accomplished by three classes of specialists. These are designated as topographic, hydrographic, and engineering branches. Topography is the basis of the work, and on it the hydrography and engineering depend. This will plainly appear when I come to describe those branches.

Topographic work is map-making. On the passage of the act of October 2, 1888, parties were immediately put in the field and work has been continued up to the present time, chiefly in the field, but to some slight extent in the office. The maps have not all been constructed, but are in part in manuscript. None of them have yet been engraved. The sheets of the map, or the several maps in detail, are constructed with grade curves, or contours, having a vertical interval of 25 feet in the valley and over the more level grounds.

Every 25 feet of elevation above the level of the sea is determined over the entire surface, and the lines on the map represent every 25 feet of change, so in passing from upper to lower heights you have a descent of 25 feet from curve to curve or line to line, as shown on the map. In the foot-hills the lines are 50 feet apart in altitude, and in the mountains they are 100 feet, and yet in any steep regions they are 200 feet apart; so they vary from 25 feet to 50 feet, 100 feet and 200 feet, depending on the nature of the declivities. Such contour maps are very easily understood and express the chief or important facts of natural topography in the simplest manner. It is thus that valley, hill, and mountain, with all necessary detail of relief, are expressed to the eyes in definite quantity. The map shows that the summit of the slope is distant from the foot of the slope say a quarter of a mile, and that the summit is 25 feet above the foot. In this manner the altitude above the level of the sea of every portion of the country is represented, and the whole form is presented at a glance. With a little experience a map of this character is read as easily as a page of print—more so; it is in fact interpreted as a picture. Such are the maps we are making, and I wish to show where they have been made under the two appropriations for the Irrigation Survey.

With the appropriations that have been made it has not been possible to prosecute work in each of the States and Territories of the region and we were compelled to make a selection of districts. In doing so it was thought best to inaugurate work in the most densely peopled regions and where the scarcity of water was most keenly felt. For this reason the Arkansas Valley in Colorado, portions of the Rio Grande in New Mexico, the Truckee and Carson in California and Nevada, the Snake or Shoshone River in Idaho, and other important districts were chosen. I place before you a map of the arid region upon which are colored the districts which have been surveyed up to the present time, and will go on to describe them in detail, commencing on the Arkansas River in the State of Colorado. All of this district as shown on the map, extending from the headwaters of the river in the high mountains of central Colorado nearly down to the Kansas line, and embracing the entire drainage, has been surveyed. We have had two seasons of work in this valley. The first season commenced in October, when there were only a few weeks of good weather left. Still we pushed the work through the winter. In the main the parties beginning in October, 1888, did not return to the office until this fall. It chanced to be a warm and dry winter in the country and we pushed the work through the cold season. The area surveyed in Colorado in 1888 was 13,000 square miles; the area surveyed the present summer was 9,900 square miles; making altogether 22,900 square miles. The area surveyed in Colorado on the Arkansas embraced all the drainage of the Arkansas nearly (but not quite) to the Colorado-Kansas line. You will see by the map to which I now point that there is but a small part yet remaining.

Other parties were put in the field in New Mexico, in the region about Santa Fé and Albuquerque on the Rio Grande, and in the region near El Paso on the Rio Grande.

In New Mexico we have mapped 6,370 square miles; in California we did 6,680 square miles; in Idaho we did no work during the last year; this summer we have, however, done in Idaho 1,900 square miles, made a topographical survey of that; and in Montana we did 5,200 square miles. So that under the act creating the Irrigation Survey and the appropriations made therefor we have already made topographical maps over an area of 43,050 square miles.

I have another map hanging before you which will set forth certain other facts bearing on this subject.

The survey under the present organization and surveys previously prosecuted under the control of the present Director of the Survey have been made with a view that they might ultimately be used for this purpose. So that we now have a topographic survey ready for the use of the Irrigation Survey of an area of 250,000 square miles, and all of that work is finished, in the field and in the office. To this must be added the 43,530 square miles accomplished by the Irrigation Survey. The maps are in part in the engraver's hands, under contract by the Public Printer, for their engraving. About two-thirds of them are already engraved, and we have proof-sheets.

Senator REAGAN. What surveys are those?

Director POWELL. The surveys previously made under my charge. All the areas in blue are surveyed in this manner, covering altogether 250,000 square miles.

The CHAIRMAN. Do you reckon in that the King and Wheeler surveys?

Director POWELL. I am going to speak of those because they are also shown on this map. The Hayden surveys are marked in light blue. Those maps were not constructed to be used for this specific purpose, but the work of the Hayden surveys was done in such a manner that some additional cost is necessary to prepare them for use for this purpose. There are about 120,000 square miles to be completed in this manner. Again, the King survey is colored yellow. The King survey is not so well adapted to this work, and more has to be done on the area surveyed by King, that his maps may be utilized for this purpose; but probably the work can be done at one-half the cost of carrying on original work. The Wheeler survey, which is colored brown, as you see, and is scattered over the country, was done in the main on a scale of 4 miles to the inch, and for our purposes we need a scale of 4 and 2 miles to the inch. Then it was not constructed in contours, and hence is unavailable for the irrigation survey. The Wheeler survey serves as a general reconnaissance for planning topographic work, but not for irrigation work. So then altogether, besides what has been done under the appropriation for arid lands, we have 250,000 square miles of map ready for use; 140,000 square miles partly ready for use; 80,000 square miles on which much work is yet to be done, and about 100,000 square miles of reconnaissance work.

Senator PLUMB. In that connection let me ask you what if anything in the shape of monuments have been put on the ground which would indicate the altitude or meandering of the lines?

Director POWELL. In the work over which I have had control myself all the triangulations of the work in blue are marked in such manner that they can be re-discovered, are marked and described in the report.

Senator **Plumb**. With the aid of these maps a local surveyor could identify them without resurveying them, I suppose?

Director **Powell**. Yes.

Senator **Plumb**. These maps would be, I suppose, what are called topographic maps, that is, they would indicate the slope and elevation, the contour, etc.?

Director **Powell**. We divide the work into three classes, each of which is dealt with; the hydrography, which describes the courses of all streams, with all their meanderings; second, the hypsography, as it is called, the elevations of all the hills and mountains; third, the culture. The lines of all high roads, of all railroads, canals, town sites, cities, etc., the boundary lines of States and Territories, counties, etc., those things which man has put on the country and are represented on the map, we call "culture." These maps represent the hydrography, the hypsography, and the culture, or that which man has put on the ground.

Senator **Plumb**. Then with the use of those maps the local authorities, or any one interested in the development of the country, would be able to understand the lay of the land just as though he himself had made the map?

Director **Powell**. Precisely; the object is to construct maps in such manner that any man may go upon the ground, take the map in his own hand, and select the sites for reservoirs, and select the routes for canals with the map before him. On selecting the routes for canals, a subsequent survey would be needed for the purpose of determining the constructive elements—the fills, the grades, the cuts, etc., that would be necessary for a canal, but the general route of a canal can be planned on the map without going on the ground. That is true not only for every canal, but for every road and for every railroad. So that wherever, in the United States, the surveys have been carried on as shown on the map, no railroad company has to make a preliminary reconnaissance or trial-line survey. From our maps all such enterprises may select their routes before they go onto the field, and they systematically do that, and have been doing it for several years, and as far as our surveys have progressed.

There is one thing of importance that I wish especially to call attention to in relation to the topographic maps. That is, that in general the reservoir sites in any region of country are in excess of the wants. There are usually more reservoir sites than will be needed. The topographic survey reveals all practical reservoir sites, and hence reveals more than will be needed. There comes then to be a necessity for a selection of the best sites. And the topographic maps furnished then practically the chief data necessary for this purpose, as well as for other purposes which I have mentioned.

I am passing very rapidly, Mr. Chairman, and briefly over these points, because there is so much of the matter. If the members of the committee wish to ask any questions as I go along I shall be glad to reply.

In planning a system of irrigation work we are at once confronted with the question, What is the amount of water to be controlled and used? The lands are abundant, the water is scarce. The entire arid lands are naturally divided into irrigation districts, each one composed of a catchment area and a farming area, for in farming regions, where agriculture is carried on by irrigation, the lands which catch the rain and supply the water are not those which are cultivated. To select from a large tract a smaller one to be irrigated, it must first be determined how much water the catchment area will furnish for the purpose, for on this will depend the quantity of lands to be reclaimed. The amount of water also determines the character of the irrigation works. More water requires larger dams, canals, and reservoirs; less water needs smaller works. The water running in the channels in each of these catchment districts—and there are many thousands altogether—is variable from year to year, from month to month, and even from hour to hour at flood time, and it becomes necessary to determine the mean annual volume, the minimum annual volume, the maximum annual volume, and the maximum volume of the floods. The mean annual flow gives the limit of general agriculture from year to year; the minimum annual flow limits the agriculture in seasons of drought; the maximum annual flow controls the plan of the works, for they must be constructed in such a manner that they will not be destroyed when it comes; the maximum flood volume also must be known, for this ultimately brings the greatest strain upon the works, and they must be constructed to withstand it.

In the plan of the survey the volume of water running in the streams of the catchment districts, and which is furnished to the farming districts, is determined by making a topographic map as a basis for a hydrographic survey.

The first process is stream gauging. The measurement of the streams is accomplished by a twofold process. First, a river-gauge is established, with a float, by which the height of the river is recorded automatically during the year. That is to say, a nilometer, as it is called, is established in such manner that the rise and fall of the stream lifts or lowers a float, and in lifting or lowering this float it records the rise or fall upon a paper by a little machinery attached to it; so that we have the record from day to day and month to month and year to year automatically recorded of the height of the stream. Then, the cross-section of the stream where the nilometer or river-gauge is used is determined for different heights of water. A continuous section from low water to high water is made, so that if we know how high the water is at any moment of the year we know the cross-section at that time.

Senator JONES. Does the nilometer show the length of time at which the river stands at any particular stage?

Director POWELL. Yes. It has clock-work, by which the whole history of the rise and fall is preserved.

Senator JONES. Does it show the velocity also?

Director POWELL. No, sir; I am coming to that. The next is the velocity of the water passing the cross-section. That varies in the different portions of the stream. It varies from side to center and from top to bottom, and it varies with every rise and fall of the river. It becomes necessary therefore to have another class of instruments, known as current-meters. By finding the mean velocity of the passing water and the cross-section of the stream we determine the volume of water passing for a given stage. Then we must find it for each stage marked upon the river-gauge or nilometer. This gives us the flow of the river. It is all plotted. If you remember, a plat of that kind was presented to you in Arizona.

With this river-gauging, then, we steadily gather the data to show how much water the river will carry—not at one time, but at all times, varying from day to day through the year.

It is in this manner that we gauge the rivers and creeks. The number of places where such "gaugings" must be made is very great. We have estimated that about 20,000 would be needed. To make that number of gaugings, each one for a series of years, so as to obtain the mean, maximum, and minimum annual flow and the maximum flood volume, would take a long series of years and would be enormously expensive. But a cheaper, shorter, and it is believed a more accurate method has been devised. This method involves the construction of a topographic map and the gauging of a few typical streams.

It is thus that attention is first called to the catchment area, and of this we must have a topographic map, which will show its superficial area, its declivities, and its altitude above the level of the sea. Other things being equal, the greater the area the greater the amount of rain caught. Other things being equal, the greater the declivities the greater the amount of water furnished to the streams, for flat lands with accumulated soils and sands hold the water back and by evaporation return it to the heavens. Lands with great declivities have less soil and sand, and their slopes gather more water into the natural channels. In the arid region of the United States there are altogether vast tracts, perhaps in all one-fourth of the entire area, where no considerable water runs off. There are other regions, altogether very extensive, where the slopes are so steep and rocky that the greater part of every storm runs down; and between these extremes all gradations are found. The water supply, therefore, is dependent upon declivity. The altitude of the catchment area is also an important factor, for within limits, other things being equal, the greater the altitude the greater the rain-fall. To obtain altitudes, declivities, and areas, a topographic survey is necessary, and the topographic survey having been made, the cheapest and best method of assembling the facts, so that they can be understood, is to construct a contour map. The entire area of the arid country—including the low deserts where no waters flow away—is composed of catchment areas. Each tract or district is a catchment area—not for itself, but for some other district, which in turn is a catchment area for still another. It is thus that a map must be made for all parts of the country but the flat deserts, and they are included in the others, and in some cases constitute the irrigable lands to be farmed, for while they are desert without water, they are the *best* farming lands when irrigated. Hence, practically, the entire country must be mapped, and the flat lands are mapped without expense worthy of mention.

Now, to make this map serve for hydrographic purposes something more is needed. A few streams must be gauged. Suppose we have found a drainage area of 10,000 square miles with maximum declivities, so that most of the water is gathered into channels and passes from the catchment area to irrigable lands below. Here, where the water is all brought together in one stream, we gauge it and find how much water an area of that size having determined declivities will afford. Now, wherever we have another catchment area with similar declivities if the rainfall is the same we have to make but the topographic map to determine the water which it will supply. It is in this manner that the preparation of a topographic map is a part of a hydrographic survey. A few streams are gauged, the general rain-fall is determined, and the catchment areas are measured topographically so as to obtain horizontal and vertical dimensions.

The next part of the hydrographic work is to determine the amount of evaporation. When water is stored in reservoirs an amount, known in a general way but not known in a very close way, is lost by being returned to the air. In order to know how much water can be saved it is necessary to know how much will be lost in this manner, and at these gauging stations we establish evaporating stations for the purpose of determining the amount of evaporation from day to day through the year. The machinery for this need not be described; it is very simple.

The next element in the hydrographic survey is the determination of the quantity of sediment carried in the water. All streams carry with them the drift of the slopes and hill-sides of the catchment area. Some streams carry much, others little. Some streams carry much at one part of their course and less at another part.

The life of a reservoir is an important factor, to be determined, and this must be determined by discovering how long it will take under the conditions to fill that reservoir with sediment. In order that this may be provided against it must be determined how much material must be removed from the reservoir annually in order to make its life continuous. The streams therefore have to be gauged for sediment, and an apparatus is provided for the purpose. Connected with these stations we have rain-fall gauges wherever we have established work of this character. The reading of the rain-fall gauges takes practically but very little time, and we can do it without expense. But in the main we are assisted in this work by local enterprise. In most of the States and Territories the people have organized weather bureaus, or some system for determining temperature, rain-fall, winds, etc. We have it so arranged that all this material is aggregated in our office. In most of the States and Territories ultimately people will work uniformly on our system. They are asking us already to take general control of their plans and are gathering the facts necessary for our work, so that we do not have to perform that work ourselves to any great extent. In addition, we avail ourselves of the material collected by the Signal Service.

Besides the organizations to which I have referred, there are individuals who of their own will have organized such observation systems for themselves; and especially I may mention, in this connection, railroad companies. So that there is pouring in upon us from all parts of the arid lands a vast amount of information in relation to rain-fall, to temperature, and to the course of the winds.

I shall not weary the committee with a detailed statement of the hydrographic stations we have established; but I have the results of the work up to the present time in tabulated form in this paper, and with your permission I will simply hand it to the reporter that it may be incorporated with my remarks.

Summary of hydrographic results.

The daily average flow in cubic feet per second has been obtained for the following rivers:

COLORADO.

River.	Station at—	Results.
Arkansas	Cañon City	Apr. 17, 1889 to end of year.
Do	Seven miles above Pueblo	May 1 to Sept. 1, 1889.
Do	La Junta	May 20 to Sept. 1, 1889.
Do	Lamar	May 26 to Sept. 1, 1889.
Purgatoire	Las Animas	May 22 to Oct. 1, 1889.
Huerfano	Hermosilla	June 30 to Sept 1, 1889.

Summary of hydrographic results—Continued.

NEW MEXICO.

River.	Station at—	Remarks.
Rio Grande	Del Norte	July 1 to end of year. (Discharges at intervals, also measurements of canals.)
Do	Embudo	Dec. 20, 1888, to Nov. 30, 1889. (Daily discharge complete.)
Do	San Marcial	One gauging only.
Do	El Paso, Tex	May 10, 1889, to end of year (complete).
Jemes	Jemes Pueblo	Mar. 20 to Nov. 5, 1889. (Discharge partially computed.)

ARIZONA.

River.	Station at—	Remarks.
Verde	Above junction of Salt River	Discharge from Aug. 15 to Sept. 30.
Salt	Above junction of Verde River.	Discharge from Aug. 1 to flood at end of Nov.
Gila	Fifteen miles above Florence	Discharge from Aug. 30 to end of year.

NEVADA.

River.	Station at—	Remarks.
Truckee	Essex, Nev	Discharge from May 20 to Sept. 30.
Carson		Few gaugings.
Purser Creek, Squaw Creek, Little Truckee, and all important tributaries.		Gauged in high water.

IDAHO.

River.	Station at—	Remarks.
Wood	Hailey	Discharge from June 23 to end of year.
Snake	Eagle Rock	July 1 to end of year.
Do	Above Fall River	One gauging.

UTAH.

River.	Station at—	Remarks.
Bear	Battle Creek	Discharge Oct. 15 to end of year.
Do	Collinston	Discharge July 22 to end of year.
Ogden	Ogden Cañon	Discharge Aug. 20 to end of year.
Weber	Weber	Discharge Oct. 15 to end of year.
American Fork	American Fork	Discharge Aug. 1 to end of year.
Provo	Provo	Discharge July 15 to end of year.
Spanish Fork	In cañon	Discharge Aug. 1 to end of year.
Sevier	Joseph City	Discharge Aug. 20 to end of year.
Do	Leamington	Discharge Aug. 20 to end of year.

MONTANA.

River.	Station at—	Remarks.
Yellowstone	Horr, Mont	Aug. 12 to Nov. 30, 1889.
Do	Springdale	Special gaugings.
Sun	Near Augusta	Aug. 5 to Nov. 30.
West Gallatin	Bozeman, Mont	Aug. 16 to Oct. 30.
Missouri	Cañon Ferry	Sept. to Nov. 20.

Also various canals, small tributaries have been gauged to furnish special data for use of division engineers.

Rain-fall measurements.

Locality.	Stations.	Measurements.
Arizona	30	June to Dec., 1889.
Colorado	10	June to Dec., 1889.
New Mexico	35	March to Dec., 1889.

Evaporation estimates.

[Monthly evaporation in inches.]

	1888.	1889.

‡ Based on 8 days' observation.

SILT.

The amount of silt carried by the Rio Grande at Embudo, N. Mex., was measured from January 15 to April 15, and by the Rio Grande, at El Paso, from June 10 to the end of the year (when the river was flowing).

Average volume of water (according to the assumption that a cubic foot of dry sediment weighs 85 pounds).

	Embudo, N. Mex.	El Paso, Tex.
	Per cent.	*Per cent.*
Minimum	.0014	.0139
Maximum	.0413	1.4167
Average	.0101	.3865

The third part or branch of the survey relates to the locating or planning of irrigation works—the engineering branch as we call it. So that we have three branches—the topographic, the hydrographic, and the engineering—under different managements, in general, in the field, needing men specially trained in each to accomplish the work properly.

The basis of the work of the engineering branch is the topographic survey and the hydrographic survey. The outcome of the work, the purpose for which it is all done, is not realized until the work of the engineering branch is finished. The organic statute of the survey provides that we shall select diverting dam sites, canal sites, and reservoir sites, and withdraw the same from market that they may remain in the possession of the General Government. It also provides that the lands to be irrigated shall be segregated that they may be obtained only under the provisions of the homestead act. All of these sites and lands have to be discovered. In their discovery, the entire country has to be overlooked or surveyed, and this is the work of topography. Usually there are many more reservoir sites than are needed and the best should be selected; for this purpose all must be discovered; water should be stored in the mountains whenever it is possible, as there is less loss by evaporation there. All the mountain reservoir sites must, therefore, be discovered; but a part of the water falls upon the foot-hills and valleys, and that also must be stored. So there must be reservoirs below, and this lower region must be examined. Wherever it is possible we must store the water away from the streams so that the reservoirs may not be destroyed by floods. But this is not always possible, so the whole ground must be studied for reservoir sites, then the stream channels themselves must be studied for dam sites.

Then there are canal sites from the diverting dams to the reservoirs and from the reservoirs to the lands to be irrigated, and these canal lines must be discovered. In any basin many possible lines may be found; the best should be selected, to make this selection all must be known. When there is more land than can be served by the water, the best should be selected; to do this all must be known. Now the topographic survey discovers all possible reservoir sites, all possible dam sites, all possible canal sites, and all possible irrigable lands, then constructs a map with all these facts shown upon it. The engineering survey now steps in to complete the work and the selections are made by an examination of the map, which is a miniature counterpart of the country with quantitative elements represented by contour lines. It will sometimes happen that two lines or two reservoir sites have advantages so nearly balanced as shown by the topographic map that a choice can be made only by a more refined examination. But in general the special sites will be discovered on the map. Now, these special sites must all be examined in a detailed manner in order that the works may be planned, and such refined surveys are expensive and it is necessary to reduce them to a minimum, which the preliminary topographic survey accomplishes—the topographic survey is a preliminary or reconnaissance survey to discover what the refined and costly work of the engineering survey must do, and is a great saving of expense.

While I can not go over all the ground which we have covered in this work, I have brought a few examples to illustrate what is done, and have brought this map with me to show what the survey will be when it is finished. I would like to have you consider first the Arkansas Valley. (See map.)

All the works on the Arkansas are not yet planned, but something has been done, and one illustration may be presented. On the Arkansas we have discovered a number of reservoir sites. This is the first reservoir which we planned on the Arkansas, and it is incomplete. Here we have a map with grade curves of the Twin Lakes, high up on the Arkansas River. These are 5-feet grade curves, showing the outlines and the outlet to the lakes. Here [indicating] is the outlet, and a section across here shows where the dam is to be constructed. In Arkansas twelve reservoirs like these have been surveyed in detail, maps drawn of them, and data secured for all estimates of capacity and cost, but the data has only been collected, and it has not yet been assembled, so that I can not report it. The Twin Lakes which you see here have a capacity of 100,000 acre-feet. That is a capacity, under proper conditions, to store water for the irrigation of 100,000 acres. The cost of the reservoir will be about $60,000, and the cost of the canal, to bring the drainage of another stream into this, so that all may be stored into one after awhile, will be about $75,000. The total cost therefore will be about $140,000 for the whole system of works, to store 100,000 acre-feet of water, or about $1.40 cents per acre-foot.

Senator **REAGAN**. By acre-feet, do you mean a foot deep on an acre of ground?

Director **POWELL**. Yes, sir; an acre-foot of water is an acre of water 1 foot deep. When irrigation, under average conditions, is practiced with economy, it is believed that an acre-foot of water will supply an acre of land for one year, and we adopt that as being convenient for many purposes.

The **CHAIRMAN**. That will vary somewhat, of course?

Director **POWELL**. It will vary very greatly. I am giving only a general and mean figure.

On the Arkansas now fifty reservoir sites have already been discovered. Of these, twelve of the most promising have been studied with much care and the data collected, as I have said, for their plans. The data collected show that we can store, on the sites for the reservoirs already selected, water enough to irrigate three times the amount of land now cultivated, so that the whole area cultivated on the Arkansas will be three times as much as that now cultivated.

Senator **CASEY**. And that total would be what, do you remember?

Director **POWELL**. I have the figures at my office, but I have not them with me.

The Rio Grande is the next that I shall present to you. The other work, as I told you, is unfinished and it would be difficult to present the real work without the figures and papers.

I now show you a plan of the work for the storage of water on the Rio Grande, immediately above El Paso. The Rio Grande flows from the left to the right of the map. The dam is to be constructed at this point [indicating a point on the right of the map] and a topographic survey has been made, not only of the sites of the reservoirs, but also of the larger part of the region above El Paso, for the purpose of determining the region of country upon which this reservoir must in dry seasons depend for its water. The maps are not constructed in the office, but the data is at hand and draughtsmen are at work on them at the present time. With a 60-foot dam this reservoir will store 537,000 acre-feet, and we expect to find water sufficientf or that purpose, but of this we are not yet sure, as the survey of the entire area is not yet finished. The estimated cost of this reservoir is $1,100,000.

The **CHAIRMAN**. That is, the reservoir, without the condemnation of land?

Director **POWELL**. No, sir; with a detailed project.

The **CHAIRMAN**. Covering all?

Director **POWELL**. Covering all. There are, running along the course of the Rio Grande, two railroads, and I have had the engineers of the survey run lines outside of the reservoir sites (for the railroads run into the reservoir sites) and to compute the cost of the construction of such roads, and have assumed that the reservoir would cost not only the amount necessary for the construction of the dam, but for the construction of lines of roads which would take the railroads out of the reservoir sites.

The **CHAIRMAN**. Does that embrace the land to be condemned?

Director **POWELL**. That embraces the land to be condemned.

Senator **JONES**. Where on this map is the dam to be constructed?

Director **POWELL**. Along here, at this point [indicating].

A final report of the irrigation district to be served by this water, will embrace, first, a map of the district where the water is to be caught, extending over the district where the water is to be used—the irrigable land, as you see; second, a map of the region on a large scale. Then plans for dams, canals, and all the engineering work necessary to go with it.

The CHAIRMAN. That will only include the portion on our side of the United States?

Director POWELL. On our side.

The CHAIRMAN. The other side will be about the same but a little larger, probably.

Director POWELL. In California we have discovered a good many reservoir sites. The best one is on the Monaco Meadows, in Kern County, which has a capacity of 320,000 acre-feet. The survey of one site has been completed, that of Clear Lake, near San Francisco. The results are not yet finally on paper. An extended reconnoissance has been made in California, in Butte and Lassen Counties, and two large reservoir sites have been discovered there. Altogether fifteen reservoir sites have been reported for withdrawal, and about forty more will be reported soon, in California. But I have them tabulated elsewhere.

In Nevada, surveys have been made on Weber Lake, Independence Lake, and Donner Lake, in the Truckee Basin, and also in Hope Valley and Long Valley, in the Carson Basin. A canal line has been surveyed, to extend for some miles above Wadsworth. It was intended at the beginning of the season this year to make a careful study of Tahoe Lake to be used as a reservoir. A study was made of it, but it was unsatisfactory and the work will have to be done over—the theory on which it was made being wrong.

In Idaho the work has been done on the Snake River and its tributaries. The Snake, or Shoshone, River, is one of the great rivers of the Western region, and a series of reservoirs has already been discovered. Here on the map is the Snake River. It heads, as you see, in Wyoming. A large part of the water of the Snake River must be stored in Wyoming, in the high mountains where the rain and snow are accumulated. In that region of country we have discovered three very fine reservoirs. The Jackson Lake reservoir, which you see here, will store 1,000,000 acre-feet of water at a cost of $250,000, or at the rate of 25 cents per acre-foot. The Swan Valley reservoir, which you see here, will store 1,500,000 acre-feet of water, at a cost of 25 cents per acre-foot. We have plans for these dams ready. The Fall River reservoir, which you see here, and which will be partly in the Yellowstone Park, partly in Wyoming, and partly in Idaho, will store 500,000 acre-feet of water with an inexpensive dam, but the cost of construction of the dam is yet unknown. Several canal lines have been run along the Snake River at different places, to find out where this water can be used. The water stored above must be used below on the plains, here, in the main in Idaho. The region of country in Wyoming and in Yellowstone Park is not an agricultural region.

Senator JONES. Is there water enough in the water-sheds of these reservoirs to fill them?

Director POWELL. Yes, there is ample water; much more than we are yet able to store.

The waters of the Snake River and its tributaries, properly taken out, and taken to the high lands, first, and recovered after irrigating the high lands and again used on the low lands—from the facts which we are now in possession of we are able to say that at least 10,000,000 acres of land can be redeemed.

Senator JONES. That is, as it now is?

Director POWELL. No; but by the utilization of the river, by canals, and reservoirs, complete. This will involve the construction of a number of reservoirs, the sites of only three of which are now planned or known, though in a general way we know of others.

I shall pass from the Snake, rapidly, to speak of the Montana work. In Montana we have done work on the Gallatin, the Madison, and the Jefferson Rivers—the rivers which unite to form the Missouri—and we have done work on Sun River to the north of them, and we have done work on the Yellowstone River, during the past season. I can not detain you long enough to explain all of these works. The plans which I have brought with me this morning relate to Sun River, and I shall be able very briefly to lay before the committee a very interesting system of works.

The general plan of the Sun River is here on a very small scale, because the topography is not finished. On the first map the course of the river, the lands that can be irrigated, and the sites of the canals are delineated.

The second map which I present shows the plan of reservoir No. 1, marked on the first map. The reservoir itself is illustrated by this map. The dam on the river is at this point. These are grade-curves of 4 feet elevation; passing from one line to another you rise 4 feet; so that anywhere you can make a section across the reservoir that will enable you to compute the capacity of the reservoir. The site of the dam is at this point [indicating]. The capacity of this reservoir is 43,000 acre-feet. The plan of the dam itself it shown on this diagram.

These maps which I now show you of the Sun River illustrate the character of the report we are going to make of that region. The first, the general topography on which are placed all reservoirs and canal sites; second, a sheet exhibiting such reservoir and each canal by itself; and third, a sheet like this (exhibiting the elements of construction in the works themselves), and all to be accompanied with text or written explanations, including the elements of cost, etc., with directions of how to construct the dam.

Reservoir No. 2, on the Sun River region, is represented on this sheet. It has a dam shown on the corresponding sheet, which I hold in my hand.

The CHAIRMAN. How large is that?

Director POWELL. It has a capacity of 65,000 acre-feet.

On the map we have a plan of the waste-weir. I need not exhibit to you all these plans; we have plans of waste-weirs, of dams, of reservoirs, and of canals, and the course of the river and a part of the topography. I think that is sufficient. I need not go into details. It is a small river and we were able to complete it in a short time.

The CHAIRMAN. Have you figured up the expense of those dams?

Director POWELL. Yes. That will be inserted in the record also. I have it in my tables.

We find that the water of the Missouri can be taken out below Helena, near a town called Toston, a very favorable point, so that at that point all the water that is not used above in the Gallatin, Madison, and Jefferson Rivers can be extracted from the river and poured out on lands of great value.

The CHAIRMAN. How much of the river is above that point?

Director POWELL. It is a very large river above that point.

The CHAIRMAN. There is a large water-shed above that?

Director POWELL. Yes, a very large water-shed. The whole of the valleys of the Gallatin, Madison, and Jefferson lie above it, and the whole drainage area from Yellowstone Park down to that place. At that place it is possible to take out all the water stored in the reservoirs above.

The CHAIRMAN. How extensive is the region that would be covered?

Director POWELL. The canal line is about 72 miles in length, and will cover a broad section of country, varying from 20 to 30 miles in width. Below that point the river cañons in places, and I do not really know much about it except from general topographical information; practically we have no engineering data on which to speak.

On the Yellowstone, the chief reservoir on which we have worked is the Yellowstone Lake, which lies in the park. A magnificent reservoir can be made out of it at a cost comparatively trifling—simply opening up 2 or 3 miles of channel below and putting in a head-gate and controlling the river, so as not to lift the lake at all, but to drain it down 2 or 3 or 4 feet each year, so that it will never be higher than it is now.

The CHAIRMAN. That would be very cheap then?

Director POWELL. Yes. The chief cost of the work will be in the construction of the canal. The immediate valley of the Yellowstone furnishes only in places favorable sites for irrigation. It is in part subject to floods now, and in part subject to cloud-bursts that strike the cliffs and bad lands on each side, and these cloud-bursts on the cliffs and bad lands destroy irrigation works below. Then there is not enough land lying in the immediate valley to utilize all the waters of the Yellowstone or any very considerable part of them when they come to be stored. We hope to be able to carry the water out near Livingston on to the mesa lands above without serious engineering difficulty.

The CHAIRMAN. What is the character of those lands generally?

Director POWELL. They are partly rolling; many of them have gentle slopes. Altogether these lands are as good as there are in the world for agriculture.

The CHAIRMAN. They are not too high up?

Director POWELL. No; they are good wheat lands. The operations of the survey have been extended in another direction. The statute requires that we shall determine sites of reservoirs—segregate them from the public lands, and report them to the Secretary of the Interior and to the land department, and under that statute they are withdrawn from sale that they might be used by the people as reservoirs. We have made a number of these selections, and all of them I have in a table before me, but I shall not read them now. It would take too long, and the matter is too statistical for an occasion like this, but I will hand the table to the stenographer, and he can insert it in my remarks. The table embraces only a very small part of the reservoir sites that have been discovered, and includes only those which the engineers have selected. Many others will be selected out of those already discovered.

COLORADO.

---

[1] This lake has been thoroughly surveyed, but reports not yet received. Office work ~~has not~~ reached stage of estimates.
[2] A very good reservoir site.
[3] A good site.
[4] A very good site.
[5] Delivery will probably be very large; present indications are that this is the most effective site now known in California.
[6] These reservoirs have been reported worthy of examination and survey. No estimates practicable at present. In a general way most of them will be costly in proportion to delivery; some probably too costly.
[7] Present indications are that these two are very valuable reservoir sites of large delivery. Not yet surveyed.

IDAHO AND WESTERN WYOMING.*

[Snake River Basin.]

No.	Name.	County.	Drainage basin.	Capacity.	Delivery.	Cost.
				Acre-feet.	*Acre-feet.*	
1	Jackson Lake[1]	Fremont County, Wyo.	Snake, South Fork.		1,000,000	Small.
2	Swan Valley[2]		do	1,500,000	1,500,000	Do.
3	Falls River[3]	Yellowstone Park.	Snake, North Fork.		500,000	Do.
4	Blind Creek	Elmore	Boisé		160,000	Do.
5	Fair Creek	do	do		60,000	Do.

---

[1] Capacity much greater than possible delivery. The delivery depends upon unsettled questions. If the proportion of precipitation which runs off from the water shed is nearly as large as in the case of Yellowstone Lake its delivery may exceed considerably 1,000,000 acre-feet.

[2] There is no question that the water supply is ample, and more than sufficient to fill this basin.

[3] Capacity probably much exceeds the inflow.

*The storage capacity in the Payette and Weiser Valleys is known to be large, but has not been surveyed. There is also a large portion of the Upper Snake Basin which remains to be even reconnoitered for sites and there is no reason to suppose that the above approximates the limit of storage possibilities in that basin.

MONTANA.†

1	Sun River System, No. 1.	Lewis and Clarke and Cascade.	Sun River.	12,000	12,000	Moderate.
	2	do	do	13,000	13,000	Do.
	3	do	do	63,000	63,000	Do.
	4	do	do	42,000	42,000	Do.
	5	do	do	65,000	65,000	Do.
	6	do	do	12,000	12,000	Do.
	7	do	do	3,000	3,000	Do.
	8	do	do	3,500	3,500	Do.
	9	do	do	2,000	2,000	Do.
	Yellowstone Lake		Yellowstone.		1,300,000	Small.
	Logan Valley		do		250,000	Moderate.
	Beaver Head, No. 1		Beaver Head.	500,000	400,000	Do.

† There are a large number of great reservoir sites not mentioned here which have been reconnoitered, but only to a sufficient extent to determine the fact that they have good dam sites, and a large water supply. Any estimate of their actual capacity and delivery would at present be premature. On the Madison River, Mr. H. M. Wilson is of the opinion that there is storage capacity with full delivery for at least 800,000 acre-feet at a low cost per acre-foot. On the Jefferson and its forks there is nearly as much. Sixty-two reservoir sites, all of which are believed at present to be practicable and moderately costly have been reported for withdrawal in Montana Their united delivery may be roughly estimated at not less than 4,000,000 acre-feet.

UTAH RESERVOIR SITES.

1	Utah Lake[1]	Utah	Salt Lake.	Very great	Not great.	Small.
2	Gunnison[2]	San Pete	Sevier	2,000	2,000	Do.
3	Bear Lake[3]	Rich	Bear River	Very great	Problematical.	Large.
4	Desert[4]	Millard	Sevier	800	800	Small.
5	Cottonwood[5]	Salt Lake	Salt Lake.	Small	Small	Large.
6	Panguitch Hayfield	Garfield	Sevier	Very large	5,000	Moderate.
7	Plateau Valley	do	do	Moderate.	2,500	Do.
8	Panguitch Lake[6]	Iron	do	25,000	11,000	Very small.
9	Marysvale[7]	Pi Ute	do	10,000	10,000	Rather large.
10	Otter Creek	do	do	25,000	25,000	Moderate.

---

[1] Surface 140 square miles; lake shallow; maximum depth only 14 feet.

[2] Projected; not constructed.

[3] Water-shed now draining into lake relatively very small; area of lake, 120 square miles. Dam site doubtful; can be filled by diverting Upper Bear River.

[4] Projected; not constructed.

[5] Valuable as possible source of supply of water for use of Salt Lake City. Too costly and too small for irrigation.

[6] An excellent site.

[7] Cost probably not prohibitory.

Senator **REAGAN**. That is a list of the reservoirs that have been selected?

Director **POWELL**. That is a list of those already selected and defined. The list is arranged by States. It will be seen that there is a large number.

Irrigable lands have been segregated in the same manner, and all segregations have been completed in Montana.

The total amount of lands selected as irrigable in Montana is 11,500,000 acres; in Idaho the total amount of land selected as irrigable is 10,900,000 acres; in Utah the total amount of land selected as irrigable is 2,200,000 acres.

There will be reported in a few days in our office for the State of California 1,800,000 acres; and for New Mexico, on the Rio Grande and in the Rio Grande Valley, 5,200,000 acres, all of land segregated as irrigable land.

I thought I would bring here our method of record. I have brought a map showing where irrigable lands of Montana are situated which have been designated. They are colored green. In the aggregate about 30,000,000 acres of land have been segregated and withdrawn from the market to be offered to the people for homestead entries, as the statute provides. There have also been withdrawn many miles of canal lines. The sites of these lines remain, under the statute, in the possession of the Government, as I understand it. In the same manner many hundred reservoir sites have been withdrawn from the market, enough to store water sufficient to supply many millions of acres.

In a very brief manner that outlines the work that has been accomplished with the appropriations that have been made in the last two years, amounting in all to $350,000. It is not all expended; there being a sufficient amount of money on hand to continue the work until the 1st of July, partly in the office and partly in the field.

The **CHAIRMAN**. What length of time would it take to do the engineering work, or how early could you do it so that the people may know where to locate the reservoirs, etc.? How long would it take to do sufficient work in each State for all practical purposes, so that they could have it in hand?

Director **POWELL**. That is a difficult question to answer; it depends on the rate of appropriations.

The **CHAIRMAN**. Of course I do not expect exactness in the answer; but I would like to know about what rate of progress you can make.

Director **POWELL**. I think it would take a long term of years at the rate at which we are now going. It would take fifteen to twenty years at the rate at which we are now going. It was understood when the estimates were made that that work would go on very much faster hereafter than now—I would like to get it all done in six or seven years. At the rate of appropriation on which the original estimates were made we ought to get the material practically ready in seven years, and one-seventh of the work can be done each year.

Senator **JONES**. With what amount of annual appropriation?

Director **POWELL**. About $1,000,000 a year; that is if we have to segregate the lands and do all those things which the act of 1888 and the subsequent act of 1889 impose upon us.

The **CHAIRMAN**. Suppose you were to leave out all except the reservoirs, and the points at which the ditches were to be taken out, how long would it require, how rapidly could you designate the reservoirs and the points, leaving out the surveys of lines further than would be necessary to designate the proper places?

Senator **Jones**. You have to have the survey made, I suppose, before you can tell definitely?

Director **Powell**. I can not do final work in any one basin without completing it all in that basin, and no part of the work is available for the people of such basin until it is all finished. We can not plan a system of works by piecemeal. We can not commence at the wrong end and plan backwards. We can not plan a reservoir and then afterward discover its site; we must know its site first. We can not plan until we know the amount of water which will be furnished to it, and by what diverting dam and what canal the water can be brought to it, and what lands can be irrigated by it, and what canals must be constructed from the reservoir to the lands. That is, we must discover the facts upon which the plan is to be based before the plan is made. We can not make the plan and afterwards discover the facts to fit it. The topographic survey must come first. The facts must be discovered by some method or other, and the topographic method is the cheapest way of discovering the facts, and the most accurate, and the most speedy. It would be possible to plan works by guessing at the facts, but when the plans were finished they would be worthless; perhaps they would be inadequate to serve the purpose; perhaps they would be extravagantly expensive because made on too elaborate scale. But the greatest danger of all would be to plan works which would not withstand the floods and be destroyed. The fortunes of the people depending thereon would then be wrecked, and in all probability many lives lost. It would be foolish and dangerous to plan the works ignorantly without regard to the facts which should govern their construction. Such a course should not be contemplated. The only question which can arise is, what is the best method of obtaining the facts; how can they be accumulated economically, thoroughly, and speedily?

Senator **Jones**. The surveys may show that such preliminary locations are bad. You have to make the surveys before you can know?

Director **Powell**. I do not think it is wise to give to the people plans for reservoirs and canals, and designate lands on which these waters may be used, until the surveys are completed, except to say that "these places are reserved." I mean as it is completed from year to year; certain areas can be ready every year, but the whole of the States and Territories would take seven years, as I have said.

The **Chairman**. We will have a number of different localities in which the people will be anxious to get to work, and a good deal of pressure will be brought to bear upon us all the time. I want to see how this can be relieved.

Director **Powell**. We propose to relieve the whole situation by taking the most densely settled areas first; then it must be understood that there is a certain amount of irrigation in every country which can go on independently of all surveys. There are small streams, springs, creeks, etc., on which the people can go ahead themselves. This general survey has its chief importance in connection with the great rivers, and with large creeks and streams, where large reservoirs may be constructed.

In some places the people's work is carried as far as possible, and where irrigation has been developed as far as possible by this means we are pushing in, first to show how that industry may be developed by the larger projects. But none of these will cut off the minor irrigation work. The major irrigation, the larger enterprises, will be developed from region to region in each State and each Territory as these regions become more important. The minor undertakings are already under way.

Senator REAGAN. Did you have any plan for distributing this work, so that the various new States and Territories may have their relative advantage?

Director POWELL. I shall estimate by States and Territories this year. The first year it was supposed to be experimental, and the matter was made at my request in bulk and not distributed, allowing me to select particular places to illustrate what could be done. The estimates will come in this year by States and Territories, so that it will be divided among them all.

Now, Mr. Chairman, on this subject I want to say something in relation to the plans. The work which we have done relates to the control of the stream water. What we have done does not relate to waters which are to be derived from artesian and other sources.

The CHAIRMAN. And it does not include storm water?

Director POWELL. It does not include storm waters. When estimates were originally made and planned for the survey, under the direction of a resolution of Congress I planned only for the control of the stream waters, and made no plan for the use of storm waters or for the use of well waters. The people of that region of country seem to demand that the other subject should be investigated. If that is done, the areas to be covered must be mapped in the same manner and somewhat more minutely, and a geological survey is necessary.

Artesian waters are found in geologic basins, where the formations are turned up—bent into basins or great geographical bowls, that hold the water, and where there are formations or strata of harder rock, practically impervious to water, and between which are sandstone or shales pervious to water. If there is to be anything done of value to the people it involves geological survey, and if that is done the basis of it is, like the rest, to be a topographic survey, for the maps are necessary. It is impossible to marshal the facts and understand their meaning without having them asemsbled on maps to show their proper relation. So that, as for the plains, they must be topographically and geologically surveyed. That will develop the basins. In addition to that, provision should be made for a little experiment in boring. As these basins are developed, experiments may be made from time to time in boring to test the accuracy of the geological conclusions. It would require, first, a geological survey; second, experimentation by boring, to be of any real and permanent value.

The CHAIRMAN. Your survey has not included boring?

Director POWELL. No; the law does not provide for geological work or survey under the appropriations for the Irrigation Survey.

Senator CASEY. What is included in a geological survey?

Director POWELL. The formations that underlie the country are to be discovered by going along the streams and by examining in that country the wells, every exposure, and every quarry for the purpose of finding strata and observing their relations, their position, where they dip under, and where they come up, etc.

Senator CASEY. That is, a geological survey involves a determination of what is under the surface?

Director POWELL. Yes; what is revealed only to the eye of the geologist.

Senator JONES. You have to make a tographical survey before that?

Director POWELL. It should be made at least *pari passu* with it; and to show the meaning of all the facts they must be assembled on maps. It is better to make it in advance.

Senator **CASEY**. But no such detailed topographic survey is necessary where the water can be found in wells, as in the case of running streams, because the water is generally used where it is taken out. Is not that so?

Director **POWELL**. Yes. The topographic survey for the use of the artesian waters is not necessary. That is a very simple matter, because that is seen by the man who stands by the well. The topographic survey for the discovery of artesian waters is another thing—not for the use of them but for the discovery of them.

Senator **CASEY**. The Geological Survey has an attaché, summer after summer, in our State, driving over the country and ascertaining all the facts, has it not?

Director **POWELL**. Yes.

Senator **CASEY**. Are not the data already collected by that attaché sufficient for topographical purposes?

Director **POWELL**. No, sir. The topographic survey which we have been conducting in that country has not been on the plains, but in the mountains. The topographic survey heretofore has been chiefly valuable to the mining people.

Senator **CASEY**. But you have had in eastern Dakota a man for several summers, at least, examining the country north and south, tier by tier, until he has been over all of Dakota; is not that true?

Director **POWELL**. For the purpose of discovering the succession of rocks.

Senator **CASEY**. Does he not take the altitude?

Director **POWELL**. Not for the purpose of making maps.

Senator **CASEY**. What I want to know is, if the cost of a topographic survey could not be dispensed with until the facts underlying the water question are ascertained?

Director **POWELL**. I think they should go on together. I do not think we could make reports satisfactory to the people without a topographic survey. The work could not be made satisfactory without maps and the map making and the geological work should go on together.

Senator **CASEY**. The one thing we and our people desire to know is, what is the extent of the artesian basin underlying that country; they care nothing for the topography of the country, because their hopes and their courage are dependent on what they ascertain in regard to the water that may be obtained. Now, as this is a question of expense, and the money to be appropriated for the purpose has to be granted by Congress, we want to make the expense involved as trifling as possible until we ascertain those essential facts. Therefore I suggest that perhaps an expensive topographical survey may be dispensed with until we know the facts about the water. Would not that be the better plan? Mr. Chairman, would not that strike you so?

The **CHAIRMAN**. We will discuss that after hearing all the facts.

Senator **CASEY**. It was by way of discussing it that I have stated what I have.

Director **POWELL**. If the artesian waters are to be discovered in such a manner that we may predict something of them—so that we can say to the people, "Bore here and you will get water," or "Do not bore there because you can not get water"—that would be of value. To do that a geological survey based on topography is the cheapest and the quickest method. If we go into that country and write books about guesses as to how the strata lie, about the sandstone and the limestone here and there without having determined definitely where they lie and at what depth they lie and as to their character, whether they be pervious or impervious to water, but go in with a general statement to the people that it seems to be a good country for the boring of artesian wells, and if it should afterwards turn out that it is not a good country for that purpose our reports would be of no practical value. Unless we should be able to say positively "Bore here, and you will succeed; if you bore there you will fail," the reports would be of no practical value.

In order to be able to say to the people "You can do this and you can not do that," you will require a map based on a survey. Geology is expressed in topographic features. The map-making collects and arranges these facts of geology in a manner the most economic. All sound geology is based on topography. No good conclusive geologic work is done in the world without this basis.

The CHAIRMAN. In passing through that section of the country the committee took all the testimony that it could get regarding the condition and the character of the rocks. Suppose now that the United States should make a reasonable appropriation for additional wells to determine the extent of that basis, and an intelligent man, a geologist if you please, were to diligently inquire and make a careful record of what had been discovered—of course your experimental wells would determine in other places—might you not with one or two intelligent men to observe and record what has been done, and with the Government making some more wells, determine with considerable certainty so that the people might see where they could sink wells, so as to be making a practical move?

Director POWELL. We can take the artesian basins that we know of. Some of these basins are pretty well discovered and defined, as I have said before. We can say to the people as to certain places, "Bore here" or "Bore there."

There are other places where the artesian basins are not well known, but experiments have been made in them. There are others it is probable now entirely unknown. We know that there are some artesian basins, but we do not know their outlines. One man bores in one place and gets no water. The money of the man who gets no water is therefore lost. To trace the outline of that basin and be able to say to the people "You can bore and get water but if you bore 1 or 2 miles away you can not get water," that we can not do until we have studied the geological structure.

The CHAIRMAN. Yes, but that takes a good deal of time. The people are on the ground. and they are boring wells. Their hope is predicated on the prospects of getting water. My idea is to aid them in what they are now doing by collecting the facts as to the penetrations——

Director POWELL. That we are doing.

The CHAIRMAN (continuing). Doing that carefully—ascertaining the levels at which they will have struck water, formulating the information as fast as possible, and giving them all the knowledge available; and then, under an intelligent man, having some Government money expended in boring other wells to relieve them of the experimental expense. I have received I suppose twenty or thirty letters from enterprising men in that section, and one from a gentleman in New York, the other day, who said that he owned some land there and wanted to sell it to settlers. He wanted to know what information there was to be had as to the developments that had been made there in artesian wells, and what the Government could do or would do. It occurred to me that it would be well if you could have somebody who was a good geologist to classify what has been done, without waiting for the topography—without waiting for the general geological survey; simply to classify what well-sinking has been done; and then to let some chances be taken, without speaking with absolute certainty, but giving them all the facts, as to where water is found. They will not want to wait until you have done all your work, so as to be able, as you say, to speak positively. They want to do something right away. The people are there and want immediate relief.

Senator CASEY. Will you be able to determine the limits of that basin without the experimentation?

Director POWELL. No, sir; not fully.

Senator CASEY. Is it not better to immediately proceed with experimentation to ascertain the expanse of those basins, instead of waiting for the topographical survey that will involve considerable time and expense? The very fact that the Government is taking an interest in this matter will be of great value to the people of that country. Their courage will be greatly aided. As to a topographical survey, the average citizen knows nothing of it. If he sees a hole being bored in the ground he knows what that means; he knows that it means business. The more important part of the country to water is the uplands, away from the river. What the people desire is that they shall know whether they can have water. Coming over this country, for instance toward the Red River, they will want to know whether they can get water, and at what expense. Can not that be ascertained by experiment, and can not the other work be followed up as inaugurated? That is to say, can not the beginning of the work be the boring of experimental wells?

Director POWELL. The work which is to be done there can be considered from two stand-points. It can be considered from the standpoint of what will be known when it is finished, or it may be considered from the stand-point of its progress—what will be known in the stages of its progress.

While the topographical work is going on, as I should work, the geological work is going on, the experimentation is going on; and the geological work is confirmed, as it is going on, by the experimentation. And when it is finished we will know the whole thing; but we will only know parts, as we finish the work in parts, as we go along. But as we go along the work will be developed *pari passu*.

Senator MOODY. The people who have sunk these wells are not scientific people, but mere well diggers. The information which they have obtained they have not preserved.

The CHAIRMAN. Some of them have.

Director POWELL. We have more facts than they dream of.

Senator MOODY. They have not the facts which would enable them, or enable a scientific man, to determine the strata and the extent of the basin and all that. Of course you are aware that right here on the banks of the Missouri River, the very southernmost point of South Dakota, they have several wells. We know the fact, of course, that they were obliged to go only from 450 to 650 feet, according to the elevation on which they started, to strike that basin which brings the water to the surface with force, and of course we know the fact, for it is a familiar one, that the pressure there is from 60 to 80 pounds to the square inch. The other day they struck a well at 760 feet at Huron. They had to go 900 feet elsewhere. They got a well at Redfield at about 1,100 feet, and so on. They had to go as far as 1,300 feet on the divide between the Jim River and the Missouri River.

Here is a quartzite stratum along the eastern side of North and South Dakota. That red quartzite which they call jasper, sometimes granite, they have attempted to go through, but they have never found any water at any depth that they have gone through that. So we call that the "rim," or the "rim-rock." No experiments have passed over the Missouri River, or over the divide, in fact they have not got quite on the divide.

Now, the query is whether it would not be advisable to put a force into the field at once for the purpose of making a fairly good survey to show what area of this country can be utilized for irrigation—to experiment with this water—to see for example whether there is anything in the water which would be detrimental to crops.

The CHAIRMAN. I think the water is very good.

Senator MOODY. And then to dig experimental wells over west and across along the Missouri. Where we get across into the western part of the country we know there is plenty of surface water, and people are using the surface water for irrigation; they are constructing ditches in this region of country. One of these ditches is 25 miles long. But going farther north, into the western part of North Dakota, we do not know how much use can be made of the waters. What we want is that these people already there on the ground—600,000 people are located there—may know where they can get water. The farmers will have to depend upon bringing water to the surface to furnish moisture either in the atmosphere or upon the lands, because there comes sometimes a series of years in which they do not have sufficient rain-fall.

Senator CASEY. And four-fifths of the people are farmers and directly dependent on their farms.

Senator MOODY. Now, as Senator Casey has said, what these people want is courage. The courage of conviction is what they greatly desire, and if the Government will give them sufficient money to dig experimental wells they will take care of the rest.

Senator CASEY. But their courage must be built on that which is palpable to their eyes. They can not be expected to look upon this question from a scientific stand-point at all.

Senator MOODY. They want results.

Director POWELL. But what shall the people be given courage to do, to bore wells where they will ultimately fail or to bore wells where they will meet with success? Suppose they are advised to bore wells on barren ground; the first failure of that kind would react and all courage would be lost. I do not wish to give the people courage to lead them on to failure, to waste their energies in seeking disaster.

Senator MOODY. Will not the expenditure of a few thousand dollars there by the Government absolutely determine the question as to where that artesian belt exists and where to bore?

Director POWELL. Artesian water can be discovered in part by experimentation and in part by tracing out the formation of the ground.

Senator MOODY. And one must go with the other, you think, or ought to go with it?

Director POWELL. Yes, precisely. The geological examination without the experimentation will more or less be futile. The experimentation without the geological examination will be wasted. That matter has been up before Congress again and again, and appropriations have been made for Texas and Colorado. Fifty thousand dollars has been expended by the Government and thrown away, and yet there are artesian waters in that State. But the wells were bored without the examination of the geological structure and were not placed where the water was to be found.

Senator MOODY. Is it not practical with a comparatively small appropriation or expenditure for you to put into that country a corps of engineers and others right at once?

Director POWELL. I have estimates sent to the Secretary for each of the Dakotas of $50,000, with the idea that the work there was pending, that it was necessary, and that they wanted the work done at the earliest possible day.

Senator MOODY. Fifty thousand dollars for each of the Dakotas?

Director POWELL. Yes.

Senator MOODY. Is that enough?

Director POWELL. I have asked for $50,000 each for North Dakota, South Dakota, Nebraska, Kansas, and Texas, to be used in this work. With that amount of money I propose to take up, first, the study of the artesian waters and storm waters. My judgment is that the storm waters will be most valuable. I want to be frank with you. I think the people are mistaken, but the people believe in the artesian wells and I am going to meet them.

Senator CASEY. And the population lies where the storm water is not available without very great expense, such as the tapping of the Missouri, or something of that kind.

The CHAIRMAN. Oh, no.

Senator CASEY. I am living in that region and am familiar with it.

Director POWELL. My idea is that the people are looking to the artesian waters, and I should push artesian examination first; but I believe that it will be but a small resource, and that the great resource will be in the storm waters and river waters.

Senator CASEY. The experimentation is different in our case, because there are facts that exist from which you may proceed, and the examination of the basin should be from what is known outward.

Director POWELL. Yes; you have artesian basins but how much water will they supply is the vital question.

Senator CASEY. That is a different thing from an examination in a country where no well has ever been discovered.

Director POWELL. Already we have facts in relation to the two Dakotas upon which we can proceed with a great deal of confidence about the artesian waters. There has been sufficient study of the geology and sufficient experimentation to make a basis from which to start.

Senator CASEY. The confidence of the country with regard to the James River Valley itself is established; but the notion exists in the minds of the people that when you have left the particular formation which makes that valley (of which they know nothing, but which they suppose is the formation inclosing the valley) they will not be able to get water. They have not the courage to expend money for wells there. If the Geological Survey will ascertain that the basin is not confined to that particular valley, experiments will go on by the people in all directions, but they must have some one thing to give them that courage.

The CHAIRMAN. Suppose that, taking the places that are known, experimental wells were sunk outside, where the probabilities are great, but where people are not willing to make the experiment, the Government money would not be wasted, would it?

Director POWELL. Some would be wasted and some not.

The CHAIRMAN. If where you succeeded and gave courage then private enterprise would take hold of it; even if you did waste some money the information would be valuable. By sinking the well the formation would be discovered as you went down. What would be the average cost of these wells?

Senator **Moody**. The well at Redfield, complete, 1,050 feet in depth, cost $3,100.

The **Chairman**. What did the well at Huron cost?

Senator **Moody**. That will cost more, although it is not quite so deep.

Senator **Casey**. That well at Jamestown cost $7,000. But there is nobody who knows just what a well is going to cost.

The **Chairman**. I should like to get at a general average, to see how much money is necessary to accomplish any useful purpose.

Senator **Moody**. Mr. Holt, whom you met at Huron, I suppose, gave the matter a great deal of attention, from the fact that he has had the management of a farm mortgage company there.. He told me that they had received an offer from a responsible company to sink thirty-five wells in that region of country for $35,000.

The **Chairman**. What would be the average depth of those wells?

Senator **Moody**. The average depth would be about 800 feet.

The **Chairman**. If they went to the higher lands they would have to dig deeper wells?

Senator **Casey**. That would be relatively more expensive. I saw Mr. Holt and other people at Huron quite late in the season, and the people on the ground were quite doubtful as to whether it could be done at that price. So that I think that you will need to reckon on these wells costing $5,000 each, taking the average of the country up and down.

Senator **Moody**. Possibly, if you reckon on the divide, that may be so.

The **Chairman**. Major Powell has got $250,000 for the plains.

Director **Powell**. Yes; if the work is to proceed on the theory that the basins are to be discovered by the boring of wells then the appropriation should be larger. If you want immediate results and want to proceed on the theory that the investigation must be made by experimentation, the appropriation should be larger and it should be expected that much of it would be wasted.

Senator **Casey**. That could not be avoided.

Director **Powell**. With that understanding we can go ahead experimenting.

Senator **Moody**. If every experiment was to be a success we would not want you to make any experiment. We would make it ourselves. It is for the very purpose of determining absolutely that it is no longer an experiment that we want this done.

The **Chairman**. The situation out there is very pressing.

Director **Powell**. If you will give me sufficient money, I can, within one year, put a corps of geologists and engineers boring on the plains, but it must be understood that much would be wasted, and when the work is finished not a very great supply for agricultural purposes will be given. The amount of water to be obtained from artesian wells is very small, but what there is will be of value.

Senator **Moody**. That is what we want.

Senator **Casey**. That is what we want, so far as North Dakota is concerned.

Director **Powell**. Many of the wells bored would be failures; others would be successes. A double corps would be needed—a corps of engineers and a corps of geologists.

The **Chairman**. There is a vast population there now that are suffering, and the Government can afford to give them courage, if it is possible to do so. If it could relieve them at once and stop their sufferings it would be a great blessing to that country, for it is really suffering. There are 600,000 people there and they have lost their courage. They want immediate knowledge in order to give them courage. They are a vigorous and active people and only want encouragement.

Senator **CASEY**. They want the knowledge that the Government is taking an interest in this matter. They want it in a palpable form.

Senator **MOODY**. Of course we know the existence of this rim-rock. I believe you call it Sioux quartzite?

Director **POWELL**. Yes.

Senator **MOODY**. It is a formation by itself. Of course we know there is a little out-crop of that quartzite on the Jim River, which is not very material, and there is nothing of it as you go west. The limit of this artesian basin, west, has never been found. In other words, it has never been a total failure to find the artesian basin. So we think, or at least we hope, that the proper investigation by scientific men—by the men that you will be able to send out—would supply sufficient facts, so that it would hardly be an experiment to dig a well.

The **CHAIRMAN**. How much of an examination would it be necessary to make to examine the Missouri River as to where it could be taken out, etc.?

Director **POWELL**. If any ordinary appropriation is made we will be able to do that next year.

The **CHAIRMAN**. I do not mean a general survey, but to ascertain the particulars?

Director **POWELL**. I understand. The single fact could be determined easily; it is a question of levels.

Senator **MOODY**. The situation of the country is such that after getting out of the influence of the Jim River, you have to take the water from the Missouri. You can not climb this ridge.

The **CHAIRMAN**. Oh, no. That is the thing we want investigated.

Senator **CASEY**. The bulk of the population of North Dakota lies east of what is known as the Coteaux.

The **CHAIRMAN**. Are you through with your general statement, Major Powell?

Director **POWELL**. Let me say just one word more, Mr. Chairman. If I beg for thorough work, which will not ultimately lead to disappointment, I want you to understand my motive in the matter. We can do work that will be valuable to the people at once, in some cases, but in many cases it would bring disappointment. If we are hurried in doing it, instead of doing it in a careful, scientific manner, many people will fail and will say "We have failed because we followed the recommendations that were given." We know of three artesian basins in the Dakotas: That on the Red River has been carefully surveyed. Its supply of water is limited; but it is in a region of country where irrigation is not necessary. Farther west there are two other basins, imperfectly known; one of them gives no evidence of being of great value; the other gives evidence of being one of the finest basins in the world and is worthy of the most thorough examination; and yet we can not hope for a great supply of water for irrigation from it. Water for towns, villages, gardens, ranches, and even for powers, may be obtained, and perhaps some small amount of water for farming purposes; but artesian waters are always limited, and excessive boring destroys them. The great basin of the Dakotas should be utilized to its fullest extent, but it must not be tapped beyond th.. or the whole thing will collapse. That has been the experience of many artesian basins; and it seems to me that it would be wise to direct the attention of the people more to the storage of storm waters. There are many portions of the Dakotas where this can be done advantageously and cheaply. Yet I do not wish to discourage the use of artesian waters to the utmost extent of the supply.

The principal supply of artesian waters in the two Dakotas is from the Dakota sandstone. All the great wells are found in it. We do not have to discover that sandstone; we know its extent throughout the country, but we do not know how much water it will yield. We do know that the supply is limited, that it can not be great; that it will be impossible to multiply wells indefinitely; and we do not know but that this source has been drawn upon nearly to its limit. Should I say to the people that this sandstone is found from north to south throughout the Dakotas and from the ninety-seventh meridian westward nearly to the Rocky Mountains, and that you can in most places find artesian waters in it—which is a fact—it would give the people courage to bore, and many wells would be immediately sunk, and the probabilities are that the supply would soon become exhausted and all existing wells destroyed. What we want to know is to what extent this source can be drawn upon and when the boring of wells into it must be stop. But what is still more important, we wish to discover whether there are any other water-bearing formations. All this can be determined in the most speedy and most economical manner by a geological survey based on topography and by an occasional experiment to verify the inferences of the geologist. The geologist is able to say that such and such rocks and such and such districts will not afford artesian waters. His first conclusions are therefore negative, excluding certain rocks and certain districts. Then he discovers other districts where the character of the rocks and the geological structure give probabilites that artesian waters may be found, and these probabilites must be tested by experimentation.

And finally, Mr. Chairman, I wish to be understood as expressing the opinion that when all the artesian waters are discovered and all utilized there will still not be a sufficient amount of water for the region of country of which we have been talking, extending along the plains from our northern to our southern boundary, greatly to affect the industries of agriculture. Artesian waters have always been and must be inadequate to meet the wants of irrigation, except here and there for gardens, orchards, vineyards, and for stock purposes. The great fields of Dakota can never be cultivated by artesian waters. To encourage the hope for success in this direction, on any scale adequate to the needs, is to give the people a false hope that will lead them to disaster. I know that the people see streams of water bursting out of the ground here and there, impelled high into the air, and in times of drought these are beautiful scenes. I know that they have reached the conclusion that there is a lake of water underground, and that rivers flow beneath their feet, and that they have but to tap these sources to receive an abundant supply. But I also know that these opinions are groundless; that the waters which they obtain are only those which percolate through porous sandstone from a long distance away, and that the supply is exceedingly limited. I know that the sandstone in which it is found is widely spread, but I dare not tell them of its extent lest they be tempted thereby to spend vast sums of money in vain, and reach still worse results by destroying the fountains already developed. It is my opinion that the resource is not exhausted, that some more wells can yet be successfully sunk into the Dakota sandstone, but to what extent it is safe to go on as they have begun I dare not say until a proper examination is made. I am not willing to deliberately face the facts before me and encourage the people as you desire.

Mr. Chairman, the discussion of this subject of artesian wells has come at the end of a long hearing, and little time has been given to it in view of its importance. I should be much pleased to be heard by the committee at greater length on the subject, and to prepare myself with maps and diagrams, that the question may be fully understood.

Is it wise to encourage the people to gamble for water with the dice loaded against them?

FOURTH DAY'S SESSION.

WASHINGTON, D. C., *January* 31, 1890.

The committee met. Present: Mr. Stewart, chairman; Mr. Plumb, Mr. Casey, Mr. Moody, and Mr. Reagan.

The CHAIRMAN. I will say to those who are here to-day that we have gone over generalities sufficiently. We have collected a vast amount of general material. What we want now is to hear from any person present who has practical ideas as to what can and ought to be done to facilitate irrigation; how it can be directly got at; what aid the Government can give most advantageously and with the least expense to make a profitable development of the arid regions. We would like to confine gentlemen to that. I would like to hear from two or three on that point. Mr. Nettleton is a practical man; and we will hear from him; also Mr. Hinton. (Addressing Mr. Hinton.) The committee would like to hear your views as to the practical methods of procedure desirable on the part of the Government to aid irrigation. We have already gone over a great deal of ground, and have collected the general history of the subject from the testimony taken throughout the country. Major Powell also has given us a good deal of the general history. We will, therefore, necessarily limit those whom we are to hear to-day to practical suggestions as to what ought to be done.

STATEMENT OF RICHARD J. HINTON, IRRIGATION ENGINEER, U. S. GEOLOGICAL SURVEY.

Mr. HINTON. In the work before us, Mr. Chairman, at present there seems to be two distinct points to be aimed at, for largely the running waters within the arid region are being daily and almost hourly consumed. By that I mean the streams and the waters in sight. The points to which I should direct then my attention would be: first, that we should aim at the conservation of the storm or surplus waters, which must necessarily be stored in the high altitudes of that region, and, secondly, the restoration for use in agriculture of the waters under the earth.

These two divisions at the present moment seem to me to be the essential purposes for which engineering efforts should be made. I suggest then that the great area lying east of the Rocky Mountains—the plains and foot-hills—from the 97th practically to the 101th degree of west longitude must come first, because of the great population that has gone in there, and of the large amount of struggle and of pecuniary effort that have been made by them; also, owing to the condition in which they are being constantly placed by reason of the insecurity or uncertainty of the water supply. These severe conditions arise not so much by the deficiency of the water supply—taking the years through—as by its unequal and unsuitable division. What we call the great plains region, then, has for the work of reclamation to be first considered, upon the ground that the largest part of the population to be benefited by irrigation are to be found therein.

The problems involved in that fact are, of course, two-fold, as in the whole field: These are the storage of the surplus waters in the Rocky Mountains proper and in the valleys of the streams flowing there, and the obtaining of an adequate knowledge of the waters within the earth, so as to make plans and lay out the best methods for their economic use in the near future.

In the two Dakotas, our journey last summer, and the evidence that has been taken by the committee, show the most remarkable artesian water-belt, I think, known in the history of the world. The statistics are very limited thus far as to its definite limits, but I have obtained a list of about forty of what I would call town-wells, having depths from 1,600 to 1,800 feet and a pressure of from 80 to 220 pounds to the square inch. These are within a comparatively limited area, which, with perhaps two or three exceptions in the James Valley, would be below a level that would allow them to be supplied from the seepage or percolation of the Missouri River. I do not say that they are so supplied, because no one can tell that at present, but the levels are such and the geological indications, so far as known, are such as to give reasonable ground for the belief that some of those wells may be so supplied.

Senator CASEY. From the Missouri River?

Mr. HINTON. From the seepage and percolation of the Missouri River. From my observation, covering many years, and of late years very closely applied, I am convinced that we know very little as to the practical extent of percolation or loss, the underflow some call it, from the waters of the great rivers flowing across the plains, and through the arid region generally. That is the field of observation that we have to develop. I believe that under this so-called underflow is in a large degree the source of a very great many of the springs and of the wells that we find in those regions.

Senator CASEY. Of the artesian wells, also, do you think?

Mr. HINTON. Of the artesian wells, also. I could not put that forward as anything more than a reasonable suggestion, because there has yet been no investigations of a character sufficient to warrant anybody in positively stating such a theory.

It has been said that we need a topographical survey for experimental work in that region. Against the able and distinguished gentleman who assumes that, I hate to place myself as hostile, but I believe that the experience of all engineers testifies that it is a fact that topography can not indicate clearly or definitely where any artesian or other water may be found. Geology certainly can help in that direction and it certainly will help. The Dakota basin seems to be geologically delimited, so that its eastern rim is well defined; its general formation is understood, and if there can be an appropriation for the purpose of definite experiment in regard, first, to the artesian water supply, its area and sources, and second, to the gauging of the great stream that runs through the Dakotas that is the Missouri River, so that we may know definitely the amount of water, of the volume, etc., that flows through its channel at any given time, we shall have accomplished a piece of work that, well done, will be done for all time, and does not depend upon a topographical survey or even upon a more definite geological examination.

If I am asked to recommend the way, I beg to suggest a considerable appropriation for these definite purposes: first, of ascertaining the character, through the boring of experimental wells, by the river gauging suggested, and by the location of tanks or small reservoirs, of the water supplies of the two Dakotas; secondly, to place the States of Kansas and Nebraska, with their Arkansas and the Platte River Valleys, in another district, find out the same class of facts therein, and in addition investigate the best manner of recovering the great body of water which sinks into the earth—the water which flowing from the mountains spreads through the broad channels I have named, and finally sinks into and is extensively retained by the stratum of gravel and sand, immediately below the soil.

There are artesian wells in northern and central Nebraska. Reaching over into northern Kansas, in the Republican Basin, will be found a large body of water lying near the surface, which can be made of great agricultural value, at little expense, by experimental work and development.

When we come to southern Kansas, we find that there has already been some work done in the way of ascertaining the value of the seepage or percolation of the Arkansas as it flows eastward. At Dodge City, though the work has been temporarily stopped by the winter storms, they have already run some 20 miles of tunnel or drift. The average fall of the Arkansas River from the mountains is about 7 feet to the mile. This insures the possibility of putting in levels for the purpose of obtaining that under-supply and distributing it over the land at no great expense.

Senator CASEY. Point out on the map the regions to which you refer, as you go on.

Mr. HINTON. This is the Arkansas River [indicating], here is Dodge City. At Dodge City they are running a tunnel in westward. The average fall from the mountains, then, is at least 7 feet per mile. The project is to take it out on either side by reservoirs and laterals, and distribute it on the land. In the counties to the south, there is a considerable artesian well region. There are a number of artesian wells in Meade County and elsewhere in that section; of this, the committee has taken evidence.

In eastern New Mexico there is an extensive region of large springs, showing the existence of water under ground that comes with great force to the surface, We find when we come to northern Texas, and to what is known as the Staked Plains and the Panhandle region of that State, that there are in existence to-day a great body of wells. Some are artesian in character, but there are many that flow so near to the surface and with such force that it is evident that if these wells were sunk deeper they would have the artesian quality; they would strike that stream. It is a general belief there, among both engineers and practical observers, that the water under the Staked Plains, the water from which these wells are supplied, has the character of a flowing stream. Some experiments have been made in the neighborhood of Marienfelt, Odessa, and Midland, on the Texas Pacific Railroad, which seem to indicate the correctness of that theory. The altitude lowers abruptly, and the land is of a totally different character. Beyond the westerly limit of the Staked Plains the land is all of a distinctively arid character, as arid as Nevada or Arizona. It has no precipitation exceeding 8 to 11 inches of fall per annum. But throughout northwestern Texas there is unquestionably a large underground water supply. The springs which come to the surface, the evidence of the wells upon Staked Plains and in the Panhandle region, indicate this. Indeed, the testimony all goes to show that there is a supply sufficient if it could be brought to the surface to answer the purposes, by small storage, of almost that entire region. The rain-fall will average 20 inches per annum.

The CHAIRMAN. You do not mean by that statement to say that it would be sufficient to irrigate all the land, do you?

Mr. HINTON. No; not all of Texas west of the 97th meridian. By no means. Of course the valleys of the Colorado and of the Pecos Rivers must largely be a surface-irrigation region, supplied by those streams. But still a large portion of the area can be supplied by a small storage system that may be made by conserving the local rain-fall from the surplus of the wells, by their storage, and by that of seepage or drainage water also. My own judgment is that on these great plains running through, east to west, between 97 and 103 degrees, in the main, small storage rather than great works will for a long period of time to come be the reasonable and safe means of supply for the people living therein.

Looking at the Great Plains region practically, and as a matter of legislative recommendation, I should say that this Government may reasonably and properly expend sufficient money to find out the water supplies thereof; to ascertain how they can be most economically conserved and used; in short, to learn definitely to what extent these plains may be made permanently available for agriculture, or whether, in fact, they must be in large part retained only for pastoral purposes. This knowledge may be obtained, rapidly and with sufficient accuracy, without the delays necessarily incidental to a full topographical survey, or even of a minute geological survey. The pioneers will go onto these lands. They should have accessible the information requisite to their proper direction.

Of course, I beg leave to say, that it is the business of legislators to see that a proper topographical and proper geological survey shall be carried on, but I do not think the Irrigation Survey is necessarily dependent on their progress. On the contrary, I suggest, with all deference to abler men than myself who express a contrary opinion, that the delays incident to their completion will result in a positive injury to the irrigation work. There are competent engineers in the Survey, and there are facts sufficiently known as a basis for their action, so that it would be possible to commence at once the work of investigation for experimental artesian wells in certain directions; the work of developing the quality and the character of the percolation of the great valleys I have named, the Arkansas, the Platte and others, the flow and character and volume of the Missouri, as it runs through these regions. All this is absolutely necessary. Engineers and geologists may arrive rapidly at proper conclusions. The railroad surveys made across the plains will give all the needed altitudes. A series of field reconnaissances can be vigorously pushed. All the preliminary facts can be arrived at in a proper manner some time before this Congress adjourns, and at a day early enough to enable it to have some definite information before it on which to base any other action that it might deem desirable. I want to add that whatever money expended experimentally on these lines will not need to be continued. A topographic survey, or rather a series of topographic maps, is not a precedent condition.

The CHAIRMAN. Your attention has also been called to Arizona. There are a large number of petitions from there for experiments such as you suggest.

Mr. **HINTON**. Arizona is a region over which I have traveled and observed almost as much, in days past, as I have in Kansas and the central region. In southern Arizona there are areas of underground supply that can be developed. The Santa CruzRiver, for example, flows under ground to Maricopa, in the Gila Valley. It runs into the Gila River near that point. The Santa Cruz River rises a few miles below the southern line of the United States, in Mexico. It runs almost directly north to Tucson. Nine miles beyond Tucson it is lost under ground, and then, for some 87 miles it flows under ground, until it enters the Gila and helps to swell that river. The valley of the Santa Cruz contains about 1,140,000 acres, a very large proportion of which, if there were water for it, could actually be brought under the most efficient horticultural use. It is a region admirably adapted for fruit. At the Mission of Tumacacori, and at Tubac, Calabasas and other places, there are the remains of fruit gardens that the missionaries planted and used. I have seen, in years past, all the semi-tropical fruits growing on farms that were maintained there against the Apaches. The Santa Cruz River should be taken out, as near its source as possible, and distributed by means of high-line canals.

The land is very fertile. The river has a great drainage area at its head. It is fed by several very important small streams on both sides, and if it were taken out and placed in a new channel, and distributed over the valley, the entire region at and below Calabasas could, I believe, for some 10 or 12 miles wide and 150 miles long, be made a perfect garden. We used to fancy in years gone by, in traveling over the Cienega, north of Tucson, that we could hear the waters running under ground. I do not know whether that was a correct inference or not. Eastward, and lying beyond the Dragoon Mountains, will be found the San Simon Valley, or plain, known in the olden days as the principal route southward of the Apaches. You can get water in the San Simon and Sulphur Valleys anywhere at from 8 to 40 feet below the surface. All through, in this low table-land, you will find wet places—the Mexicans call them cienegas. There are a number of ranches in that valley now supplied by such waters, from either wells or tanks and ponds. The San Pedro River also, between the San Simon and the Santa Cruz, rises in Mexico, as the Santa Cruz does, and can be, by storage near its head, made of much greater service than is now the case. Upon the plateau on which Tombstone is situated they have some artesian water, and I understand there are two flowing wells at that place.

Crossing into New Mexico, over the Chiricahua mountains, and beyond the eastern foot-hills of that range, you reach Deming and the table-land around it. Water has been found there from within 25 to 40 feet of the surface. It is an important railroad junction. It is so near that slight pumping brings it to the surface, and makes it valuable for the small irrigation, for fruit and gardens, that is going on in that region.

From what I can learn in relation to it, it would be possible to develop the whole well or artesian water-power there, and create a small storage system which would bring a large proportion of that mesa, or bench land, under cultivation for grass and root crops, as well as for fruit. Through this region and up to the lower foot-hills, water can almost always be found a short distance from the surface. Most of these little valleys of that region could be reclaimed by the use of small storage.

The **CHAIRMAN**. What have you to say as to Salt River and the Gila, and their valleys?

Mr. HINTON. The Salt River and the Gila are necessarily to be developed by large systems of irrigation. I do not believe that the Government of the United States will have to expend any large sums of money in the direction of assisting Arizona or the capitalists who may interest themselves in the reclamation of those two valleys. When I first visited Salt River, years ago, there was considerable land in the hands of small farmers with little ditches. The same thing can still be seen in the Mesilla and the Rio Grande Valley. Within a few years, as the evidence taken last summer will show, the Salt River Valley has passed under the control of a large corporation. The supply is better managed and of a much better character. If their propositions are carried out it will still further increase. There is probably no region, even in California or any other State within our borders, that presents a larger future as a horticultural or fruit-raising region than the valley of the Salt River and the valley of the Gila. On the Gila there are points where storage reservoirs should be maintained—at the buttes, near Florence, and above. Large irrigation systems are always desirable.

This region through here is a cañon region [indicating on the map]. It is not itself of much use for agriculture or even for pasture, but it is of great service as a source of water supply. In this region [indicating] the irrigation would be accomplished largely by local storage, some of which will be quite extensive, as at Walnut Creek; but it will be what in the future will be known as a secondary system. It will not be the high altitude storage system.

In regard to high altitude work we must bear in mind that what we now really know of the precipitation over the whole of this region relates more to the valleys and the table-land than to any other part. All the meteorological or weather service reports that we have had have been simply for the purposes of local trade and traffic. We have had no system of observations of a definite and distinct character in regard to the mountain ranges. The rain chart presented in the last census by Mr. Gannett, and of which I have a copy here, and which has been improved by later observations, shows that the only record we have of rain-fall definitely from the ninety-eighth degree to the Pacific Ocean will range, going from the east to the west, from 20 inches down to 8 and 9 in the basin, and up again to 18 and 20 or 24 on the Pacific coast. At some points it will fall as low as 3, 4 and 5 inches. This is the record at Yuma, in the Colorado Desert, at Mojave and elsewhere. We know as a matter of fact, though not from a recorded series of observations, that the rain-fall and snow precipitation on the mountains is as from 3 to 5 inches in excess of what it is in the valleys below. The average snow-fall on the Sierras will be from 60 to 70 feet of loose snow, giving us on the basis of 11 inches of snow to 1 of water from 5 to 6 cubic feet of water. All, or nearly all, of this water runs to waste. At least 90 per cent. of it passes away in evaporation, or largely in the ground. The largest portion disappears below.

The first great feature of an irrigation survey proper will be the conservation of these storm-water supplies. I take it for granted that it is not necessary to accompany a survey for that purpose by an attempt at an accurate topographical survey of the lay of the land. I have never seen or heard of any country in which a topographic survey has been considered a condition either precedent or subsequent to successful irrigation. The chief objects, then, of a United States irrigation survey to my mind are, first, to delimit, so as to be known of all men, the drainage areas; secondly, to define the available reservoir sites within those areas; and thirdly, to indicate the channels by which they can be most economically distributed when made.

So far as the Government of the United States is concerned, it being definitely understood that there is no work of construction to be undertaken, the object that it should have in the establishment of an irrigation survey is to achieve those definite and distinct points, the delimitation of the drainage areas, the definition of the reservoir sites, and the indication on the maps, the simplest and clearest that can be made, of the leading, most economical, and safest methods of storing and subsequently distributing the waters that are to be conserved.

The work I have indicated as that which in my judgment should be done east of the mountains would be largely in the way of experiment. Some of it might fail; other portions of it would, I believe, succeed. I do not know positively; no one does; but I believe so. But, when the wells are once sunk so that we have found the definite basis of supply; when the rivers and streams are gauged; when we have examined into the question of the value of the percolation of the great streams like the Arkansas and the Platte, the money expended on that would have settled the questions at issue. The encouragement which will be thus given to industry and effort will be quite sufficient to induce private capital to go in with them. Behind that and beyond it the work of the great storage basins must go on. Each drainage basin is supplied in the main only by its own local precipitation. We do not get any more water practically than falls upon it. In, therefore, developing such a region as the Arkansas Valley, while we do not necessarily now have to establish, and might not this year or the next have to establish, the high storage basins, we must expect to see them developed and completed finally in order to insure continuous security and safety to the entire valley.

First, then, I would take the Arkansas Valley as one practical fact. I would take the valley of the Rio Grande, which is in peril, as another. Both of them, owing to the great snow-storms of the passing winter, may be very well situated next summer, yet all the time they are in peril. This is owing to the use of the water in Colorado, the State wherein they both rise. The proper use of the Colorado use is water. It is necessary to develop the facts indicated by the Director of the Geological Survey. I believe they are facts. In the Rio Grande Valley there will be found to be a series of great storage and drainage basins, each portion of which can be served by its own high altitude precipitation by the snow and storm waters stored in the mountains that mark the drainage rims and outline these great basins.

Utah comes next in my judgment. The people of that Territory have developed the primary forms of irrigation in a manner and to an extent unknown elsewhere in the country, but they have reached pretty nearly the limit of their capacity in that direction. And with the recurring arid or dry seasons they are always in danger of losing their prosperity through the loss of crops. They have 600,000 acres of land under water, and usually irrigate that much. Last year, as the testimony before your committe shows, not more than 350,000 or 400,000 acres of that land were in cultivation. Utah needs deliberate and definite work in regard to defining and delimiting, as I have said, the drainage areas and their reservoir sites with a view to the encouragement and support of those people. It will also need some work in the development of the underground supply, because in the basin of Utah Lake and elsewhere to a limited extent there is an underground supply produced by the drainage of those great waters, and the United States might profitably spend a little money in testing the capacity and extent of the areas thereof.

The same is true of Nevada. Nevada, perhaps the chairman will permit me to say, is looked upon as rather the lost sheep of the American Union; as having very little capacity for anything now except the possible discovery in years to come of a new bonanza. I do not hold that opinion, and I have passed much time traveling through Nevada in the last fifteen or twenty years, and have studied it closely, and I believe it is possible to make Nevada, by a comparatively moderate expenditure, by means of the reclamation of its arid lands from water supplies that are in sight, a State that will support a population of at least a million of people in the comfort which irrigation produces to the community wherein it is practiced. I should like to say here that farming by irrigation produces a more comfortable life, more prosperity, and, so far as my observation goes (and it extends from America to Egypt and from there to China), it produces more food supplies, more sustenance from the land, and brings more comfort, prosperity, and certainty to those who work by it than any other system of farming does. It makes the production of food almost as certain as the weaving of cloth.

I have gathered a few items regarding Nevada which will take but a moment or two to state, because there are some problems involved there in the question of reclamation that need consideration.

The area of that State is 71,737,600 acres, of which the water area is but 1,081,600 acres. The timber is estimated to cover 2,600,000 acres; the pastural area is estimated to be 30,000,000 acres, the mineral area 15,000,000 acres; the desert and saline deposit, 3,656,000 acres, and the agricultural area is placed at 20,000,000 acres. That is the area to be reclaimed, if water can be obtained.

The State board of reclamation appointed to consider the question of irrigation therein, in the report embodied in your testimony, presents a series of statements by counties, which will show an area of 17,981,000 acres as possible for reclamation, of which area 2,198,000 acres can, in their judgment, be reclaimed by wells and springs that are known to exist. In Esmeralda County, in the southwest, there is an area considered to be reclaimable, and also in White Pine and in Nye County, in the southern and eastern part of the State. There are sixty-five artesian wells in Nevada. The average altitude of the State is considerably over 4,000 feet above the sea-level. It is a mountain bowl, surrounded by high ranges, and the fact that there is found even that limited number of artesian wells would indicate the necessity at least of examining into the character of the drainage or underground water supplies. There are a large number of important springs.

The trouble with Nevada is, in the main, that the drainage area that will most surely supply the water needed for reclamation is found largely within the limits of other States and Territories. In the north, the rivers head up in the northerly and northwesterly territories. On the west, the easterly slopes of the Sierras are unquestionably part of the drainage area of Nevada. I am not speaking of political lines, but of the natural features. The great lakes that lie upon the Sierra Nevada are mainly upon the eastern slope of those mountains and the waters naturally and properly belong to the people of Nevada. Take Lake Tahoe, 78 square miles of its surface (that is, two-fifths), are within the lines of the State of Nevada; the remainder is within the lines of the State of California. Lake Tahoe is ranked with navigable waters and belongs then to the Federal Government. It is all on the eastern side of the mountain. The ranges rise from 3,000 to 6,000 feet above it. Lake Tahoe has a drainage area of at least 1,200 square miles; the valley of the Truckee has a large drainage area. From Lake Donner and the other lakes that are known along that range water can be obtained. Lake Donner has been surveyed and its boundaries meandered. It is now reserved for irrigation purposes. Sufficient water can be obtained for western Nevada without the loss of a single cubic inch to California. By the storage of water in the mountain lakes alone enough can be obtained to reclaim from 1,000,000 to 3,000,000 acres of land. Even if it be but 1,000,000 acres it will amply repay all its cost and double at once the values of the State.

That land is worth nothing, or very little more than nothing now. It would be worth from $15 to $30 an acre if it were watered. That would make as prosperous a community as could be formed within the borders of the Union. Nevada was born during the war, and by her mines hundreds of millions in precious metals have been added to the general wealth of the country. The larger proportion of those who have benefited by that development have left Nevada to struggle through the poverty and indifference that are now surrounding her people. I think it is within the range of legislative action to consider whether this child of the mountain and of the war can not be benefited by some special work and special appropriation to carry on that work. I hold that Nevada stands first with New Mexico and the Dakotas, with Kansas and Utah, as among the earliest regions to be considered.

The committee will understand that I am an officer of the Geological Survey, and that I am not placing myself—not intending to, at any rate—in direct opposition to the Director in any of my suggestions. I design only to do my duty to those on whom falls the responsibility of legislation. I am obeying orders to me imperative. My observations and my knowledge then, such as they are, lead me very strongly to the conviction that a topographical survey, a platting of the entire arid region upon the scale of 4 or 20 feet to the square mile, is absolutely unnecessary for the carrying on of an irrigation survey such as I have understood Congress to have designed in the making of its appropriations. I have seen irrigation practised from Utah to Egypt and from California to China, and I have studied its entire history, but I have never yet seen or learned of a region in which a topographical survey was a condition precedent or even subsequent, so far as success was concerned.

I believe the Irrigation Survey should take on very largely the feature of a great reconnaissance, conducted by civil engineers competent for that purpose. I have in my own mind framed a little idea as to what it might possibly cost to put such a work for the next year under way. Of course, I do this without having that definite knowledge of the administrative needs which come only from the direction of a large office and of the handling of the expenditures thereof.

I have placed the total appropriation at $750,000, of which I should expend, or should indicate the expenditure of, $350,000 for the development of the underground water supply—the wells and the river underflows in the region lying east of the mountain. The other $400,000 I would expend in as rapid and as complete a series of surveys as possible—surveys or reconnaissances by proper engineers competent for that purpose. I think that ten or twelve such parties could be put into the field and practically a large part of the work of delimiting and defining could be done. The need of rapid work is shown by the fact that seven-tenths of the arable portions of our remaining public domain is now found within the arid region.

The Irrigation Survey divides into three parts, as a method of administration, in my mind: First, the civil engineers, whose work it is to obtain the information; second, the hydrographic engineers, whose work is of a delicate and important character, in the ascertaining of the water supplies, their extent, their volume, etc.; and third, the creation practically of a new division, which has never yet, in any large sense, been attempted. We want a small corps of trained observers in climatology. We ought to have a small number of stations at least, in the highest altitudes in which they could be placed with safety to those who are to work therein. We ought also to have an appropriation large enough—it would not be a great amount of the total—to encourage the taking of volunteer observations in mining and lumber camps and in other places where labor and human habitation go on in those high altitudes, and we should have some persons to superintend and to gather and obtain this knowledge. It has been suggested to me by a gentleman who has studied this question and is familiar with the work that $10,000 or $12,000 expended properly in that direction would be as beneficial as anything that could possibly be done.

This is not simply weather service observation. Weather service observation is a minor division really of the greater service suggested. What is needed is the study of climate in its largest aspects; in these regions and under those circumstances that will bring the most return. First, then, I say, that an irrigation office wants a competent civil engineer and staff; second, it wants a competent, but small staff of hydrographers, and third, it wants a small staff of students or observers in climatology.

Senator REAGAN. Would you not extend that to the valleys as well as to the mountains?

Mr. HINTON. I would, of course; but the valley observations can be properly carried on by the Signal Service, now in existence, and so that there could be perfect co-operation. A very large proportion of the lower altitude work can be carried on by a little extension of the present weather service machinery, but the law and appropriations for the present machinery do not embrace that of which I am speaking—they are not intended to embrace it—they are not designed to cover it, and Signal Service men are not properly or particularly well trained to do it. I would simply supplement their work and bring the two into harmony. That is why I say it does not require a very large sum of money.

In carrying out the work of an irrigation survey during the present year, at least, it is not necessary to press this class of work in the regions where the population, so far as is known does not immediately demand it. I should aim to carry that work out in the regions where it is mostly to be required for immediate necessities. I have indicated in part what those are. At the same time I believe it will be possible within three or four years to close up entirely the field-work of the irrigation survey proper. If I am not mistaken the topographical survey, which is doubtless a necessity for the future, which every great country will carry on, and should carry on, is a question of time, so that if the irrigation work is to depend on the progress of the topographical survey according to areas covered as presented here it would take some twenty years or more to complete it at the present rate of expenditure. It would take less than that at a larger rate of expenditure, but it would take not less than $8,500,000 or $9,000,000 to complete in conjunction with the irrigation work a topographical survey of the region west of the one hundredth meridian of longitude. It is estimated to cost $5 per square mile, and I have heard so competent an engineer as the able officer in charge of the irrigation survey declare that he can do the work needed for 1 per cent. of the lowest cost estimated for a complete topographical survey.

I think, then, that this topographical work may well wait on the progress of the population and the growth of wealth. I do not believe either that it can now be done with that sufficient accuracy by the means now in hand that will warrant the attempt. The makers of maps who have had the handling of the topographical maps made by Wheeler and Hayden, and others in the West heretofore, find the grossest errors. At various times I have been told of localities in which a difference of as much as 1,000 feet has been found. The topographical survey that is now being carried on is certainly in the largest sense a much more accurate attempt at that work than has ever been attempted before in the country. But it can wait, as I suggest, upon the progress of population.

I want to call attention, if I may be allowed to do so, to the necessity of action on the part of Congress at this present session with regard to the boundary matter and the international dam at El Paso. It was once my fortune to live in that city for twelve months. At the time I thought it was an ill fortune, but I have got over that idea since. I have traveled through northern Mexico a good deal and have studied the condition of the people there, and have been up and down that valley and I know something of the circumstances that surround it.

Unless some action is taken to definitely determine the boundary-lines between the Republic of Mexico and that of the United States at the point where they come together at El Paso and below it is quite certain that there will be continued trouble, disorder, and want of peace from year to year. It is not a question primarily of irrigation; it is a question of international obligation. Under the treaties of the United States the people of Mexico are entitled to certain rights. Under the circumstances which surround the flow of the water in the Rio Grande they are deprived at present of those rights, and they are deprived not by their own action, but by the action of that portion of the American people who live within the upper boundaries of the Rio Grande. It is not, of course, an intentionally hostile action, but its effect is the same. It is therefore necessary that action should be taken. There have been, as you are well aware, surveys made and plans devised which are admirably adapted for the establishment of an international dam and reservoir at El Paso. In a little publication which I have received this morning (I think it has not been made a matter of record even) Major Mills estimates the total cost of the dam—the purchase of the land and the railroad removals that would be required——

The CHAIRMAN. I think Major Powell gave those figures.

Mr. HINTON. The total amount is $1,007,599. I did not know whether they had been given.

So far as the survey is concerned the work has progressed. I take the liberty of urging that such legislation be had as will bring about at an early day the appointment of an international commission for the purpose of settling that difficulty. I shall be glad to answer any questions which the committee may ask.

Senator CASEY. In the matter of experiments, in my State, for instance, how many wells would you guess would be required to make that test as to the extent of the irrigation basin?

Mr. HINTON. Colonel Nettleton, who is the engineer of the Rocky Mountain portion of this present survey, is here with us, and I think he can give you, because he is an experienced well-man, a better hypothetical statement than I can.

Mr. NETTLETON. I never was in Dakota in my life.

Senator CASEY. Major Hinton has made certain estimates of the proper amount to be expended for work of that kind. There should be some basis for those estimates. Of course work in our country would depend entirely on the number of wells necessary to be put down. As he has named an amount that would be proper for the work, I suppose he has given some thought to that.

Mr. HINTON. I would myself suggest this: that a special appropriation be obtained at once for the purpose of putting it into the hands of the proper persons and making a reasonable inquiry into all the facts, and reporting thereon, at the earliest moment. I have the names of some forty wells.

Senator CASEY. Mainly in South Dakota?

Mr. HINTON. Yes. But there is hardly a single fact upon which we can predicate any definite statement.

Senator CASEY. Do you know the depths of those wells?

Mr. HINTON. Yes; we have the profiles, and can give the widths across. We know the geological formation, largely, and can obtain very much of that information. Some of it can be obtained here without going to Dakota.

STATEMENT OF E. S. NETTLETON, SUPERVISING ENGINEER.

The CHAIRMAN. Please state to the committee your occupation, and whether, in your profession, you have had experience with the work of irrigation; if so, how long.

Mr. NETTLETON. I have been for forty-five years in the profession of civil engineering—twenty years in irrigation and hydraulic engineering in the West, mainly in Colorado. For the last twenty years I have been connected with the Department of Irrigation, mainly in Colorado. I have been connected principally with large corporations, and for four years I was State engineer in Colorado, creating and organizing the department of water engineering. I have also assisted in draughting our State laws relating to irrigation. I joined the United States Irrigation Survey last May, as supervising engineer, for the eastern half of the arid country.

The CHAIRMAN. I wish particularly to inquire, from your experience and knowledge of the country, what is the best and cheapest way, from an engineering point of view, to complete a survey sufficient for the uses of agriculture by irrigation, also how it can be most speedily prosecuted and with least expense—in fact, what ought to be done to secure such a survey and what is necessary to accompany it.

Mr. NETTLETON. As I understand the law upon which the appropriations are made for this purpose, it seems to me that the whole of this work can be accomplished by what I would call an irrigation engineering survey—including sufficient topographical work and sufficient hydrographical work. It seems to me that the whole can be done under one head or in one department——

The CHAIRMAN. Would you have the engineers do the necessary topographical work as they proceeded?

Mr. NETTLETON. Simply do what topographical surveying is necessary—not surveying any pasture lands or mining sites outside. The hydrographic work is a part of irrigation engineering, and that can be done under the same management. So I do not see any necessity for separating or making three divisions, all working separately from each other in the field, none knowing the work of the others until the next year, perhaps longer.

It is a fact that the engineering work is dependent largely on the hydrographic work. In many localities we find a large number of reservoirs and it is a question whether there are not more reservoirs than water. It is only by the hydrographic work that we can determine whether the basin is too large. The hydrographic and the topographic work should go together.

The CHAIRMAN. Suppose you should reserve temporarily more reservoirs than are required, and you found you did not have water sufficient, you could only utilize those that you had at first water enough for; the others could remain reserved, and if you found, by experience, that there was a deficiency of water supply, and you got people into the country, then you could make other reservoirs and increase your supply. It would not be necessary to know the full extent of the rain-fall, etc., before making the reservation.

Mr. NETTLETON. I was basing my suggestion on doing the work in the quickest time possible and with the least money.

The CHAIRMAN. That is what I want to get at—the Government work that should be done to enable the people to carry out the rest.

Mr. NETTLETON. In the arid country the first thing would be the finding of reservoir sites—ascertaining their extent and estimating the capacity of the dam to impound the water. I believe it is in the law that we are obliged to make estimates of the cost. That necessitates the making of a thorough survey.

The CHAIRMAN. Of the reservoir sites?

Mr. NETTLETON. Yes; also of their capacity. I think it is also necessary to have the drainage matters established. Then it is necessary to run the preliminary lines of high-line canals.

The CHAIRMAN. You would not make a working survey, but run the general lines and leave monuments.

Mr. NETTLETON. I am not certain whether the law does not require the cost of these irrigation canals, and if it does, it needs something more than a rough high-line to determine the cost of an irrigation canal.

The CHAIRMAN. If they had a reservoir site set aside and the high-line run, the people then could understand the situation.

Mr. NETTLETON. Yes.

The CHAIRMAN. Might not the estimates of cost on the ditches be postponed and that work done afterward?

Mr. NETTLETON. Yes; I think that if either was dropped out the estimates of the cost of canals might be.

The CHAIRMAN. Might be postponed?

Mr. NETTLETON. Yes; I think it would be well to make surveys of the reservoirs so as to make pretty close estimates of the cost.

The CHAIRMAN. And of the high-line ditch?

Mr. NETTLETON. Yes.

The CHAIRMAN. Then the people would go into it and make their own estimates of the cost of the other parts?

Mr. NETTLETON. Certainly.

The CHAIRMAN. What expenditure, if you have estimated it, would be necessary per annum, to prosecute this work with vigor or as fast as it is required?

Mr. NETTLETON. Covering the whole arid country do you mean?

The **CHAIRMAN**. Yes, leaving out the experiments for wells, because that is temporary, and we have to estimate that separately. I mean for a survey for the arid country, locating reservoirs and indicating the lines of ditches—how much per annum would be necessary to carry on that work?

Mr. **NETTLETON**. That will depend on the time given to complete the work. The best and most economical way would be to extend it through a series of years—five, eight, or ten years—beginning in a small way with small appropriations and gradually increasing the appropriations as we get a better knowledge of what to do. This is all new work to all of us, and my idea would be that commencing in a smaller way and feeling our way along. would be better than to expend a large amount at first, part of which might be useless.

The **CHAIRMAN**. And you would use that money where the immediate demand is to arise, for use by the people?

Mr. **NETTLETON**. Everything else being equal, I would.

The **CHAIRMAN**. You would distribute it then in different localities, where they have population?

Senator **PLUMB**. That is, you would use the money in sections where people are already on the land rather than to entice them into new areas.

Mr. **NETTLETON**. Yes; I would try to develop that country where the people are—where it is possible to do so.

The **CHAIRMAN**. You would develop the inhabited localities?

Mr. **NETTLETON**. Yes; and if such development was not possible I would let the people know it.

The **CHAIRMAN**. I wish you would think it over carefully and particularly, then make a short statement in writing after you have looked over the field, and see where money is required. You have a knowledge of the country and how money can be expended to advantage. Give us a short paper on that. Take your time to do it.

Mr. **NETTLETON**. Do you wish me to name the localities and the amounts?

The **CHAIRMAN**. The amounts that would probably be required, yes.

Mr. **NETTLETON**. For one year?

The **CHAIRMAN**. For one year.

Mr. **NETTLETON**. I will do so.

STATEMENT OF EDWIN WILLITS, ASSISTANT SECRETARY OF AGRICULTURE.

The **CHAIRMAN**. The committee will be glad to hear any statement you may have to make that is of interest in regard to irrigation.

Mr. **WILLITS**. You sent to the Department of Agriculture last summer, Mr. Chairman, inquiring if we had any information on this subject. I will simply say that from the time I came to the Department irrigation was a matter of great interest to me. The first question I asked was, what was being done about it. I called upon the heads of divisions for information. They reported to me, and I had it in writing, but unfortunately it was on the general subject. Some of the gentlemen have come here this morning with information in writing. I do not know that we have anything to say in reference to the specific questions that you want answered.

I desire simply to emphasize the fact that the Department of Agriculture is highly interested in the subject. Some of its chiefs have been across the country this year, but they have not, after all, specific knowledge. Their knowledge is general; therefore we can not answer many of the questions that you desire. I would like, however, to present the papers, and you can file them. We did not come here to make speeches, but to gather information for ourselves on the subject. I have nothing further to say except this: Colonel Hinton has referred to the absence of any study of climatology. I have seen the perfect weakness of all the information we have now on that subject. It is the great impending question in the Department of Agriculture.

The whole weather service has been confined to the mere skirmish of weather forecasts, etc., without studying the great broad question of climatology. I will emphasize what the colonel has said, that the subject is much broader than the question of ordinary rain-fall.

The CHAIRMAN. Is your Department doing anything in that line?

Mr. WILLITS. Nothing. To tell the truth we are waiting to see whether the weather service is to be transferred to us. If it is, one of the things that we shall do will be to organize it in that direction.

The CHAIRMAN. It seems to me that the weather service, if it is to extend all over the country, should be placed in your Department.

Mr. WILLITS. I have nothing to say on that subject, but I have simply said that if you do not transfer the weather service to us, and we should come at the next Congress and ask that you give us the power to study this question and its effect on vegetation and plant life, I hope you will do so. It is a great question. It is the most important question pending as a scientific and practical question. I have merely spoken of it because Colonel Hinton has referred to it.

Years ago I was very much interested in Colonel Hinton's Report on Irrigation. We had no information except what his report furnished to us. So I wrote a letter to you, asking that in some way or other that report might be incorporated into the report of this committee in some shape, modified as it might be. It is full of instruction generally.

That is all I have to say this morning, except to add that I would like to be permitted to have some papers filed.

I would also like to have Professor Fernow make a statement on the subject of forests. I should also like to have Doctor Merriam talk a little to the committee on ornithology and mammalogy—on the question of what effect irrigation will have on animal life and bird life—what new animals will probably be brought in or old ones driven out by irrigation. I do not ask that he be heard to-day, but at any time at your leisure.

Doctor Riley made a very important report on the influence of irrigation on vegetation and on Rocky Mountain life. I will present that also.

STATEMENT OF B. E. FERNOW, CHIEF OF THE FORESTRY DIVISION.

Mr. Chairman and gentlemen of the committee, you are discussing here a question of the building of a stable, and my subject has only to do with the feeding of the horse. That question you have overlooked. It is a question it seems to me of considerable importance, and, although apparently subsequent to the building of the stable, I think it will be desirable to take it into consideration, as it will become absolutely necessary to feed the horse when you have him.

I do not want to go into any discussion of the relation of the forests to water supply, but the practical question whether it has any influence or not has been called into doubt. The intelligent and practical man who does not wish to listen to arguments on the subject can go and see what other nations have done. France, Italy, Germany, Austria, all have done something for irrigation. The people of France have expended $50,000,000 for reforesting their country, for water supplies, and propose to expend $50,000,000 more. They expend it on a very small part of their territory—the southeastern mountains only. The effect of the work that they have done has shown that it was the proper work.

I call the attention of the committee to the fact that this work is being done, because propositions have been ventilated as to the desirable effect of getting rid of the forest area which the United States possesses. Italy, a small and poor country, has found out that 1,000,000 acres of their mountain districts must be reforested, and in their budget will appear $1,000,000 for their forests alone. Austria has found out that a portion of her territory must be reforested. Prussia, with a very good forestry department and area, expends $250,000 every year to rebuy the waste lands which must be reforested. All those countries are spending these large amounts of money through their forestry administration. France appropriates $5,000,000 a year for the forestry administration. Prussia appropriates $6,000,000 a year for the same purpose. I call attention to this only to show that these nations that are poor and must look after every penny, having no surplus to expend, expend this money because they deem it absolutely necessary. The United States has 70,000,000 acres of forest. They pay no attention to it. It is being devastated and burned up. That is the only point I was anxious to make before the committee.

But with regard to the feeding of the horse. I believe it is now well established that it is not so much a deficiency of rain-fall in the arid region or so much a deficiency of water supply as it is the difficulty as to the amount of water that is being lost by evaporation. In Denver there are 60 inches of evaporation and 49 inches of deficiency. That is about the way it is throughout the whole arid region. The question then is, when you have the stable and the horse, where will the feed come from. Anything that will decrease evaporation is of importance And it is important that it should be attended to now, while it is possible to preserve that which will decrease evaporation—namely, our forests.

In order to aid in looking after those in the broader areas you should have timber belts all through your arid region to help irrigation.

The CHAIRMAN. The great problem now is to reserve the timber belts that we have and to preserve them from the dreadful destruction by fires to which they are subject each year. The fires in summer make alarming havoc in the forests. This committee rode from the Yellowstone, where we struck the mountains, in Montana, to Tacoma, through so thick a smoke, for 1,000 miles, that we could not see a mountain on either side. Have you anything practical to suggest as to how, before the country gets settled up, and gets it under control, as they do in older countries, to check those forest fires? Have you studied that question?

Mr. FERNOW. Yes.

The CHAIRMAN. Have you mentioned it in your report?

Mr. FERNOW. I have done so in various reports, though I do not think I have done it in this report. It can be done, however. It is only a matter of good-will. It has been said that it could not be done on account of the expense. We have the money and we have the people. It is a very easy thing in mountain regions to control a large area with a small force, even against fires. It would be easy to use fire for the purpose of checking fire. By burning over some parts at the proper time, taking proper pains to have guards established in certain belts, whenever a fire should break out—and it will be impossible to prevent it—there should be a possibility of controlling it. At present it is a lack of possibility of controlling these fires that makes them so detrimental and makes them sweep over so large an area.

The forestry people have proposed for Canada a system of guards—a body of Government servants. The Government of Ontario has adopted the proposition—has appointed certain forest guards, whose duty it shall be to look through the country, each guard having his beat and putting out any fires that may be detected, the Government acting in co operation with the lumbermen. One-half of the expense is borne by the lumbermen and the other half by the Government. The appointment of the men is made by the Government on the nomination of the lumbermen. The Government in Canada owns the forest area and only leases out the right to cut the timber.

Mr. Fernow submitted the following paper:

DEPARTMENT OF AGRICULTURE.
FORESTRY DIVISION.
Washington, D. C., June 30, 1889.

SIR: In obedience to your letter of April 21, referring to a request of the chairman of the Senate Committee on Irrigation, I have the honor of submitting the following report on those points of the inquiry which fall more more or less directly under the observation of this division, namely, in answer to the following proposed questions:

(5) The area of timber land within the dry section of the United States, west of the hundredth meridian.

(6) The extent and effects of tree planting.

(7) The influences of forests and forest culture on the conservation of water and their known or probable effects on the distribution of the water for irrigation purposes.

The time which could be devoted to the preparation of this report having been exceedingly brief, not much new material could be brought together, and the report is, therefore, mainly a condensed restatement of what has been discussed before in various reports from this division. In fact, the statistical material on hand for the answer of these questions is only meager and does not allow much direct and positive statements, which may cover the ground in all cases, nor could I attempt to use the material on hand exhaustively without unduly lengthening the report. Most of the report is therefore devoted to the general discussion of the relation of irrigation schemes to forcs conditions, and to a statement, as concise as possible, of what is known of the influence which the forest exerts upon water conditions.

In the form of appendices I have tried to furnish more special answer to the questions propounded and information which leads to their answer.

I append, also, as containing information directly bearing upon the subject of this report, Bulletin No. 2 from this division, which gives detailed information on the forest conditions of the Rocky Mountains, and a copy of my Annual Report for 1888, which discusses at length one of the claimed forest influences, namely rain-fall.

Through the courtesy of Mr. Abbot Kinney, late chairman of the California State Board of Forestry, I am enabled to append a clear and concise statement of the forest conditions and forest influences experienced in southern California. Thanks are also due for statements received from Col. E. T. Ensign, Forest Commissioner of Colorado; and G. C. Bracket, secretary of the State Horticultural Society, Kansas; and from Prof. Mark W. Harrington, of Ann Arbor, well known as authority in meteorological questions.

It is to be hoped that the subject of the relation of forests to water supply, as yet but little understood in our country, will receive the attention which its importance in connection with irrigation problems deserves, and that this division will be enabled to make a more careful survey of the forest conditions of the region and their relation to water supplies than has been possible with the limited means at its disposal.

Respectfully,

B. E. FERNOW,
Chief of Forestry Division.

HON. EDWIN WILLETS,
Assistant Secretary.

THE RELATION OF IRRIGATION PROBLEMS TO FOREST CONDITIONS.

By B. E. FERNOW.

The following report has been written under a full realization of the importance which the discussion on the relation of forest-cover to water conditions must assume at the present juncture.

The importance and magnitude of the investigations into the problem of irrigation for the Western arid regions can not be overrated; it may be likened to the discovery of a new continent, not by a lucky adventure, but by knowledge, skill, science, and art.

In such an enterprise every factor bearing upon the problem must be carefully considered, every means which may help to increase and properly utilize the scanty supply of moisture must be employed, if we expect to produce the highest attainable result, if we intend to bring the largest possible area into fruitful condition.

The main question of the problem is, by what means can the precipitation falling over the area comprised in the arid region be made to do the most duty? And the special proposition to be discussed in the following report is whether, in what manner, and to what extent a forest cover may be expected to assist in the thorough utilization of the precipitation and atmospheric humidity for agricultural purposes; although, in the consideration of a great national enterprise which like the one proposed is to promote the development of a poorly timbered or treeless country, the significance of the forest in all directions, as a source of raw material, of health, of comfort, etc., should also find proper recognition.

The relations of water conditions of the earth and vegetation in general is graphically expressed in the words of a poet who speaks of "Afric's arid sand where nothing grows, because it does not rain; and where no rain does fall, because there nothing grows."

This interdependence of vegetation and moisture conditions has been experimentally proved; it is only an apparent paradox when we say that the presence of vegetation is at the same time a necessary condition of its existence.

This is especially true of the forests. The forest, by its growth, creates its own favorable conditions of growth. The treelessness of the plains and of much of the arid region may possibly explain itself in this way. By the destruction of the forest which originally covered this region, the very condition of its existence and of its natural recuperation was destroyed; and thus in a reverse manner, reforestation of parts by artificial means may make natural reforestation over the whole area possible by and by.

"A tree by itself is doomed where a forest once established is comparatively secure."

The failures in forest culture on the Western plains may be considered mainly due to the fact that tree-planting and not forest planting has been attempted.

The discussion of forest influences has, unfortunately, become a popular one, before a proper and positive basis has been established for it by scientific investigation and observation. This is unfortunate, because the consequence has been that extravagant claims have been made by popular writers without proper basis, and, on the other hand, the overstatements have created a distrust in the offices claimed for the forest, even in the minds of some scientific men. The very popularity of the theory of forest influences seems to be sufficient reason for these to deny and scorn their existence. A competent writer, presenting a popular treatise on this subject, says, with proper emphasis, "Nobody is entitled, at the present stage of our knowledge, to declare the question of forest and water settled one way or the other. Nobody who has not the fundamental knowledge of meteorological science and scientific observation is entitled to participate in the discussion, and the public at large, especially, can only be called upon to study and reflect, but not to take sides in blind partisanship."

Unfortunately, again we are called upon to act upon the strength of our convictions in this question; we are called upon to conserve, perpetuate, and husband carefully our remaining woodlands, on account of their influence upon climate, soil, and water conditions; or else to disregard this claimed influence.

Those who doubt the existence of such influences—some of which are proved beyond doubt—should not forget that the first conception and rational explanation of the existence of forest influences originated with the profoundest student of nature that this century has produced—Alexander von Humboldt—and such able observers as Buffon, Boussingault, and Becquerel sided with him; and in our own country the ablest writer on the subject, George P. Marsh. Let them also consider that forest destruction is the easily and readily accomplished task and is the tendency of mankind, while forest conservation is possible only to the rationally-thinking, the civilized, and progressive man.

It is, therefore, at present, still the duty of a government to give preponderance to the weight of opinion on the positive side, which seems well supported by experience as well as argument, and to shape its policy accordingly.

Considering the relation of forest conditions and irrigation problems with reference to the special case of the arid regions of the West, the writer, after much study and a hurried and partial inspection of the ground, feels justified in stating briefly and boldly, without being able to argue them at length, the following conclusions:

(1) Reforestation on the plains and forest preservation on the mountains is of greater national concern than the location of irrigation reservoirs.

(2) While the location, construction, and systematic regulation of such reservoirs, under Government control is, under given conditions, feasible and desirable, their purpose will be better subserved, if, at the same time, attention be given to forestry in connection with the irrigation systems.

(3) While forest preservation and extensive reforestation not only are coadjutators of irrigation system, but supply in part the conditions which irrigation and reservoirs are designed to accomplish, neither the one nor the other will invite private enterprise, at least for a long time to come; on the other hand, the location of irrigation reservoirs and ditches has been and will be, as need arises, accomplished by private enterprise. This statement is made without disparaging any attempts on the part of the Government to assist such private enterprise and to give it systematic direction.

(4) Certain difficulties and dangers which attend the construction of reservoirs will be increased by continued forest destruction in the mountains, induced by the neglect on the part of the Government to rationally administer this valuable property of the nation; and these dangers and difficulties will be avoided or reduced by a national forest administration and reforestation.

Such conclusions are based mainly on the assumption that a forest cover exerts certain influences which affect conditions of water supply and other climatic conditions.

When considering these influences, especially with reference to agricultural pursuits, it is a mistake to discuss them separately, since vegetation does not depend on any one factor of climate, but is rather the balancing of several factors which produces favorable conditions of growth. Vegetation does not, as is so often stated, depend on rain-fall—certainly not on the mean annual rain-fall—but on conditions of atmospheric as well as soil humidity and conditions of transpiration and evaporation respectively.

The simple mechanical impediment, then—a timber-belt or even a single row of trees opposed to the progress of a drying wind—is sufficient to affect the crop under the shelter of a windbreak, lowering the rate of evaporation and transpiration.

Therefore agriculturists in regions with plenty of rain-fall yet find it advantageous to have recourse to irrigation in order to supply the exhaustion by rapid evaporation and transpiration. The wonderful growth of the Sequoias on the Pacific coast and Sierra Nevada finds certainly not its explanation in the amount of rain-fall, which in the former locality is less than on the Atlantic side, and occurs nearly all in winter with hardly any in summer. But the mists and fogs coming from the ocean reduce the rate of evaporation and help to economize the moisture of the soil during the long period of vegetation. One of the most important studies in connection with irrigation problems will be that of the rate of evaporation and of the influences promoting or retarding it.

In this direction hardly any data are as yet collected, and we can hardly anticipate how much a single "chinook" of twenty-four hours' duration may waste the water of a reservoir or dissipate the snow which lacks the protective forest cover.

If, as is claimed, there has been observed in the plains region any effect of tree-planting on water-supply, it is most likely this mechanical effect which the timber-belt or wind-break exerts, allowing a better utilization of the moisture by the crops. At first sight this mechanical shelter may appear of too restricted a character to deserve notice, yet many facts concur in showing that it is a most important element in local climate. According to Becquerel, a simple hedge 6 feet in height will give protection for a distance of 70 feet; and, according to Hardy, a belt of trees every 300 feet will defend vegetation against the action of the wind. Every traveler in the prairie will have experienced the calm which a small growth of shrubs not higher than 6 feet creates, while the wind is blowing many miles an hour outside of this shelter. Quite a number of instances can be cited where the crop thus protected had outlived the parching blast from the South, while the neighboring field was destroyed by the rapid evaporation. In fact, this influence of a wind-break as a mechanical barrier to the progress of winds is so well understood that it requires no discussion, no argument.

That a timber-belt, and more so a succession of timber-belts, will afford so much better protection is evident.

Thus, if no other influence were conceded to the forest in the plains, this one, which tends to conserve the moisture within the range of its protection, would make systematic forest plantations a most desirable adjunct to irrigation systems.

Summer and winter drought, *i. e.*, rapid evaporation, is the bane of the farmer in the plains; and this is due to the continuous dry winds, which can be checked by rationally disposed timber-belts.

Another merely mechanical influence which needs no argument or discussion with the observer of natural phenomena, is that which the forest cover on the mountain-sides exerts in retarding the melting of the snow and the drainage of the water, thus prolonging the period during which the same may be made available. Complaints that the snows do not lie as long into the summer as they used to, before the forest-cover was removed, may be heard all along the eastern Colorado Slope, where irrigation has been practised in the most rational manner and the waterflow the best observed. By the rapidity with which the water now flows off the bared mountains the effectiveness of the ditches is reduced by four to six weeks, there being an accumulation of flow at a time when it can not all be utilized and a dearth later on when it could well be used.

Some one, evidently but little conversant with the economies of nature, has suggested that in connection with the reservoir system it would be desirable to remove the forest cover, so that the snows may drift into the cañons, there to slowly give up their waters to reservoirs and ditches. Even if the favorable results thus anticipated could be reasonably expected to follow, the dangers invited by this method of storage are simply incalculable. These have been over and over again, and *ad nauseam* pointed out in various reports, and the consequences of deforestation have so palpably been experienced by European countries not only, but even in our own, that it seems a waste of energy to rehearse them again. They are briefly the following: First, more rapid melting of the snows, especially under the marvelously exhausting influence of a "chinook;" secondly, the more rapid flow of surface waters, which carries with them the thin mold and earth, gradually baring the rock and ending up in the creation of destructive torrents, which in France have carried débris over fertile lands 150 to 200 miles into the plain, to correct which an expenditure of more than $50,000-000 has been necessary. By the destruction of the natural storage which the forest offers for snows and rains, giving up their waters gradually and for a longer period, we invite floods and droughts alternately.

The conditions, in the Rocky Mountains at least, are quite similar to those of the French Alps, and, in fact, the experiences, although only limited on account of the undeveloped state of their territory, have been quite similar, especially around Greeley and Colorado Springs. Among the dangers and difficulties which attend the construction and maintenance of reservoirs are, in the first place, their incapacity of taking care of flood waters and their liability to unforeseen bursting. In regard to both these points I call attention to the experiences of French engineers, related in the "Annales des Ponts et Chaussées," some of which are also given in George P. Marsh's classical volume, "The Earth as modified by Man." These dangers are particularly increased by the conditions of rain-fall in the region under discussion, the rains being occasionally very heavy and in the nature of cloud-bursts. Professor Harrington reports one such cloud-burst which resulted in a flood, carrying away miles of railroad track on the level at the base with such violence that the rails were bent. The recent experiences in Pennsylvania, Virginia, and other parts of the country will serve as testimony of the force of such water accumulation.

The reservoirs must be built on such contingencies, and a study of the cloud-bursts in the irrigation area is therefore highly desirable, especially as they are not as yet matters of regular record. That cloud-bursts, like all violent exhibitions of meteorological phenomena, seem to occur more often in large unwooded areas, may also point again to the employment of reforestation, as a preliminary or concomitant of the construction of irrigation reservoirs in the prairies and plains, as a measure of protection.

The following passages from good authorities exhibit pretty well the relation of forest cover to irrigation problems.

Mr. Hubert Vischer, engineer to the State Forestry Board of California, uses the following language in his report to the board:

"The agricultural development of the uplands of the coast range—and there is little else but uplands—will be as dependent upon irrigation in time as are the lands of the southern portion of the State now.

"Referring to our notes upon the general hydrographic conditions of the range, it may be inquired how water can be procured? The location of the main streams being depressed and their grade slight, to bring water upon uplands would imply outlays which the value of the lands will never warrant. Storage of water in the tributary streams and gulches can not succeed, owing to the precipitous slope of their channels and the consequent lack of storage depth. Storage of water upon higher-lying lands may, in special cases, succeed, but generally will be unfeasible, as the arable lands which it is sought to water are themselves in most cases situated at considerable elevations. Wells and the development of springs will be found, like the last expedient, only applicable in exceptional cases.

"Of all the means of storing water only one remains—nature's own means. It is only necessary to prolong the flow of natural channels for a short period—a month or a fortnight would often suffice—and to accomplish this is within the power of being effected by stimulating tree growth upon very limited area of ground, especially if due regard be had for impounding snow where practicable;" and Mr. E. S. Nettleton, former State engineer of Colorado, says in regard to forest conditions and water supply: "The fact that our system of farming has changed within the past few years by substituting for the summer crops those which require water earlier in the spring and later in the fall, makes it more important than ever to secure as uniform a flow of water in our irrigation streams as is possible to do throughout the whole irrigating season.

"To accomplish this end, I call your attention, first, to the importance of the preservation of our mountain forests, and the recovering of the mountain districts with a new growth of timber. The details of how this work is to be accomplished, and the arguments proving the benefits to be derived therefrom, I will leave for abler ones to discuss. I take it for granted that some will say, 'This forestry subject is one of the future; we want something of immediate benefit and relief.' While this may be true in part, yet the protection and preservation of the mountain forest of the present day is an immediate necessity, if we desire to protect our streams from an intermittent and diminished flow.

"Neglecting to take steps toward preserving the forests and encouraging the recovering of the mountain sides with timber, because we can not see immediate and profitable returns, is no good excuse.

"We should do this much for the benefit of those who are to follow us, and who will make this country equal at least to any of the irrigated countries in olden times, which history tells us have supported a much denser population than is possible to support in a country where the people have to depend on rain-fall for a more or less successful agricultural industry."

Another important influence of the forest, in connection with irrigation problems, is its tendency to raise the water-level in its immediate neighborhood; a well established fact.

The forest influences, which may reasonably be claimed to exist, have been discussed in my report for 1886, which is herewith appended. Such forest influences are claimed to exist in the following directions:

(1) On sanitary conditions.
(2) On local climate.
    (*a*) On temperature conditions.
    (*b*) On humidity of atmosphere.*
    (*c*) On distribution of rain-fall in time, and, locally perhaps, on quantity.
(3) On soil conditions, on water-level, and on water-flow.

The question of forest influence on the amount of rain-fall has been discussed at length in my report for 1887 also appended; from which it will appear that there are no data as yet on hand upon which the questions may be even qualitatively settled.

There is one point to which the writer would call special attention and which has too often been lost sight of when discussing the influence of the forest on climatic conditions, namely, that the condition of the forest itself plays a very important part in determining its influence. Such conditions are given in the extent, the density, the position, the composition of the forest and the age or height of the tree.

It has been very generally overlooked that these conditions of the forest are of greatest moment and may alter absolutely the nature of the influence, so that the exact opposite of the expected influence may become apparent; when, for instance, a forest on the leeward of a water surface deprives the open land beyond of the benefit of this water surface.

The influences exerted by the forest can, almost all, be referred to the mechanical barrier which it interposes either horizontally or vertically to the action of the sun or the winds, or to the percolation of water; hence the nature of this barrier, its extent, density, and continuity must needs determine the nature of its influence.

In conclusion, the writer deems it proper in this place to call attention to the culpable ignorance of the bearing which the forests of the Rocky Mountains and California have upon the water supplies and irrigation problems, as exhibited in the management or rather absence of management of the same on the part of the Government. This matter has formed the basis of the appended report on the forest conditions of the Rocky Mountains, where the deplorable state of affairs has been set forth in unequivocal language.

---

*Definite statements of the observed influence of deforestation on the conditions of atmospheric humidity will be found in the report of Hubert Vischer to the California State Board of Forestry, where the effect of the removal of the redwood forests around Humboldt Bay is noted. This report deserves special attention for the clear and business-like manner in which it treats of the present conditions and future of the north California forests and their relation to the development of the country.

It would be indeed a most irrational proceeding to promote the establishment of irrigation reservoirs, without at the same time arresting the irrational forest destruction which is invited by the neglect of Government to administer its property rationally.

APPENDIX A.

AREA OF TIMBER LAND WITHIN THE DRY SECTION OF THE UNITED STATES WEST OF THE HUNDREDTH MERIDIAN.

This section comprises regions of widely different character topographically and climatically, and the distribution of forest areas is accordingly a different one in the various regions.

PLAINS REGION.

The plains region, which may be said in general, to comprise the area east of the 7,000-foot level, is practically without timber lands; the only trees are found lining the banks of the larger streams, sometimes in clumps or even groves of from 100 feet to one-half a mile in width, the species found belonging to the Atlantic forest and consisting mainly of cotton-wood, elm, green ash, box-elder, hackberry. Going westward even these fringes of trees cease and the only occasional trees seen are cottonwoods.

This timberless region may be estimated at, roughly, 400,000 square miles.

The only mountain islands within this region, which are forested, are the Black Hills in Dakota and Wyoming, with about 2,400 square miles more or less wooded, and some of the mountain ranges in southeastern New Mexico of similar extent.

Altogether it would be difficult to find as much as 2 per cent. within this vast area that shows what may be fairly called a timber growth.

ROCKY MOUNTAIN REGION.

The area of the Rocky Mountain region proper has been carefully canvassed and set forth in the accompanying report on the forest conditions of the Rocky Mountains.

From the data given in the report, the following table is constructed, which approximates the ratio of mountain land and plains and gives the forest area which is found in the region by counties. From this we find, that of the 269,881 square miles which fall within the mountain region proper, 22.23 per cent. is reported as timbered, representing 60,075 square miles (38,400,000 acres).

MONTANA.

Mountain forest, 8,285=11 per cent.

SUMMARY.

	Square miles.	Acres.
Total area	468,851	300,064,640
Total mountain area	269,881	172,723,840
Total plains area	198,970	127,340,800
Total forest	65,470	41,900,800
Total mountain forest	60,075	38,448,000

Mountain forest equals 22.23 per cent. of total mountain area.
Mountain forest equals 92 per cent. of total forest.

INTERIOR BASIN.

The area of timber land in the States which partly make up the Interior Basin is approximately as follows:

Washington.—Total forest area estimated at 30,000 square miles. The bulk of this lies in the eastern part of the State west of the Cascade Range. The counties which may be referred to as parts of the arid region, the timber land in which is confined to the spurs and ridges and to the east slope of the Cascade Range and to the Blue Mountains, namely, Spokane, Whitman, Walla Walla, Columbia, Yakima, Klickitat, contain approximately 6,500 square miles or 23 per cent. of their area more or less forested. The interior, however, is entirely destitute of tree growth, the few trees along the rivers having mostly been cut. The yellow or bull pine is the main timber, with red fir, hemlock, spruces, and other conifers added on the better sites.

Oregon.—The total timbered area of the State is estimated at 30,000 square miles, confined mainly to the Western mountain ranges and the Blue Mountains in the northeastern part of the State.

The counties which fall within the dry section, namely, Umatilla, Union, Grant, Wasco, Lake, and Baker, a total area of round 63,000 square miles, have about 12,000 square miles timbered, or less than 20 per cent. Yet, with the exception of the forests of Wasco and Lake Counties on the eastern slopes of the Cascades, the timber growth is mostly open and scattered, even on the Blue Mountains, and the trees of stunted growth. Yellow pine, red fir, and larch are the principal trees, with lodgepole pine on summits.

Idaho.—With the exception of four counties—Kootenai, Lemhi, Nez Pérces, and Shoshone—which belong to the Rocky Mountain region proper, or are otherwise climatically outside of the dry region, the rest of the State, with over 60,000 square miles, may be considered part of the Interior Basin. This part contains of timbered land an estimated area of 9,140 square miles, or about 13 per cent. The bulk of this lies north of the Snake River; the counties south of this river may be said to be almost timberless, containing less than 1 per cent. of forest area in confined localities and of scattered growth.

Utah.—The area west of the Wahsatch Range with round 30,000,000 square miles may properly be considered as part of the Interior Basin and counted practically timberless, excepting a few mountain ridges which bear a stunted growth of juniper and piñon in their recesses. The forest area of the State which is found in the mountain ranges and on the high plateaus extending in a southwesterly direction, is estimated at 6,000 square miles, or less than 12 per cent. of the area within which it is found, the timber being found of inferior size and quantity and mostly confined to the cañons. The Colorado River plateau is for the most part untimbered.

Arizona.—The total forest area is estimated at round 15,000 square miles, or less than 14 per cent., and is confined to the high Colorado plateau above the 7,000-foot level, where a considerable body of continuous though open timber growth is found, and to the mountain ranges in the southeast. Along the streams and cañons are also found scattered deciduous trees. The yellow pine is the most valuable timber tree. The southern part shows in its tree growth Mexican types like the acacias, mesquites, and others. A scrubby growth of oaks and junipers furnishes needful fuel for domestic use and in mining operations.

Nevada.—This State, as a whole, is treeless, the most barren and naked in the whole region, with less than 3 per cent. or only 3,000 square miles bearing a timber growth, and that of little account, except around Lake Tahoe, where it has been, however, largely cut. In other parts the tree growth is confined to the recesses of the mountain ridges in the central and southern portions of the State, consisting of a stunted growth of *Pinus flexilis* (white pine), scrubby piñon on the lower slopes, mountain mahogany, and occasional junipers.

California occupies part of the Interior Basin, with portions of all the counties which cross the Sierra Nevada and which mostly also form part of the Sacramento and San Joaquin Valleys. A separation of the area of timber land which occupies the region under discussion from that on the Coast Ranges and Sierras, is well-nigh impossible.

The southern counties of California south of the interior valleys, with about 50,000 square miles, are estimated to have 1,000 square miles timbered, occupying the cañons and the tops of mountain ranges above 3,000 feet. The area absolutely or nearly timberless east of the Sierra may be calculated at about 23,000 square miles, of which perhaps 2 per cent. has a timber growth on the mountain ridges and slopes. The interior valleys, comprising a total area of about 34,000 square miles are more or less timbered; 4,000 to 5,000 miles may be estimated as entirely destitute of timber, and 15 per cent. of the balance—or 4,500 square miles—may be considered well timbered, while an open growth of oak of little value is found to cover, more or less, all the land that is not cleared.

There are, however, no data on hand which allow even a reliable estimate of these conditions. The map of the State Forestry Board of California, which promises to analyze the forest areas, is not yet available for this report.

APPENDIX B.

THE EXTENT AND EFFECTS OF TREE PLANTING IN THE DRY REGION.

Forest planting, or rather tree planting—for the planting is as yet hardly anywhere done in such a manner as to deserve the name of forest planting—has been practiced to a limited extent; enough, however, to show that it can be done, with or without irrigation, if properly attended to. The twenty-five counties of Kansas which are entirely and seven more which are partly within this region, report 39,810 acres of timber trees, seedlings, and older plants, growing in 1888. Most of this is cottonwood, walnut, honey locust, green ash, box-elder, elm, hackberry, catalpa, mulberry, Osage orange, and some few other varieties; all of the Atlantic forest trees have been grown successfully. Some successful tree planting has also been done without irrigation in Colorado and Nebraska west of the one hundredth meridian, but its extent is not known. A small amount of timber planting has also been done in the region of the Interior Basin, and a larger amount in California, where groves of considerable extent are in existence.

Statistics, from which to estimate the area of artificial timber, are not on hand outside of those given for Kansas. A canvass, to ascertain how many plantations over 5 acres in extent there were in existence, was attempted two years ago, but the returns give, evidently, no reliable result, and are therefore here omitted.

It would seem that the entries under the timber-culture act should furnish, at least approximately, an idea of the area planted to timber, but since it may be said that the majority of these entries have not only changed hands and thus appear in the annual statement repeatedly, but have also been changed to entries of other kind, no result can be obtained from the study of these figures.

The status of timber-claim planting is exhibited in the appended table. From this it will appear that 38,985,910 acres were entered under the timber-culture act up to June 30, 1888. This should represent a planted area of 2,436,620 acres, if the law were complied with and the entries not changed. Allowing ten years for timber-claim planters to prove up their entries (the law places it at eight years, allowing extensions on account of failures), the entries of the first six years—from 1873 to 1878—alone give us some point of comparison for the estimation of result. During that time 4,394,256 acres were entered, while only 783,838 acres or 17.8 per cent. of these entries were proved up, representing an area assuredly planted of less than 50,000 acres.

It is asserted that a better percentage will be obtained from the entries of later years. Altogether, however, the consensus of unbiased testimony goes to show that timber-claim planting, as a rule, does not produce the results sought after and has mostly been used as a means for speculation in Government lands.

There is also considerable planting of wind-breaks and groves done on homesteads, which is said to be attended with better results.

Altogether, however, the amount of tree planting is infinitesimal if compared with what is necessary for climatic amelioration, and it may now be recognized as well as later, that the reforestation of the plains must be a matter of national enterprise, which can not be expected from the individual citizen.

The reforestation of the plains as well as the preservation of the forests on the Western mountains, is, in fact, of greater national concern, and requires in greater degree national action than the proposed irrigation surveys.

As to the effects of the tree-planting on climatic conditions but little can be said, and the statements of opinion which refer any climatic changes to this factor must be taken with caution. There is, however, one influence which can be claimed without dispute, that of breaking the force of winds locally and protecting houses and single fields that lie within the cover of a windbreak or grove against the deleterious influence. I call especial attention to the observations on this point in the appended letter of Mr. Kinney. The experience there recorded is that had in all parts of the region, and records are on hand showing the distance to which a windbreak would protect a field against a burning southwester, while the neighboring unprotected field would succumb to the blast. The consequence of this mechanical action of the trees would also tend to diminish the rate of evaporation. This is probably all the effect —and one not to be underrated—which is due to the tree-planting in extensive shelter-belts and occasional small groves. To produce considerable changes in temperature or increased precipitation, the planting is done in too small parcels and the growth not old enough, and is also mostly too open to effect that marked difference of insolation over the forest and the field which makes the former a factor in climatic influences.

To produce great climatic changes the operations must be on a larger scale, more contiguous, and with more intent to shade the soil than has been hitherto the practice.

In this region are situated several military reservations, which could be devoted to no better purpose than planting them to forest many sections at a time. Such planting would not only furnish an incentive for imitation by settlers and supply them with plant material, it would improve conditions in the immediate neighborhood and form a nucleus for the national forest administration, which is now a necessity and whose inauguration can only be a question of time.

Entries under timber-culture act.

Years.	Initial entries.	Final entries.
	Acres.	
1873	50,246	
1874	851,225	
1875	493,694	
1876	607,984	
1877	520,673	
1878	1,870,434	
1879	2,766,573	
1880	2,193,184	
1881	1,763,799	
1882	2,566,686	23,371 acres, or 46.5 per cent. of entries of 1873.
1883	3,110,930	97,836 acres, or 11.5 per cent. of entries of 1874.
1884	4,084,464	91,600 acres, or 18.5 per cent. of entries of 1875.
1885	4,755,006	90,301 acres, or 14.8 per cent. of entries of 1876.
1886	5,301,309	141,694 acres, or 27.2 per cent. of entries of 1877.
1887	4,224,398	204,620 acres, or 10.9 per cent. of entries of 1878.
1888	3,735,305	134,416 acres, or 4.9 per cent. of entries of 1879.
	38,985,910	783,838 acres, or 17.8 per cent. of entries first six years.

	Acres.
Entries first six years	4,394,256
Entries last ten years	34,591,654

The year 1882 was the first in which, under the terms of the act, final entry could be made. The original act of 1873 required 40 acres of every 160 to be planted with trees, "not more than 12 feet apart each way." By an amendment of 1878, only 10 acres of every 160, and the same proportion for smaller sections were required to be planted, but 2,700 trees were required to be planted on each acre instead of the 302 under the original act; and on final entry at least 675 thrifty trees were to be growing on each acre. The amendment was made applicable to all final entries, obliging those who had made entries under the act of 1873 to have trees enough growing at the time of final entry to make the number of acres required by the act of 1878.

Original and final entries under the timber-culture laws from 1873 *to* 1888.

Total number of acres entered from 1873 to 1888, inclusive, 38,958,558.45.

Total number of acres entered from 1873 to 1880, inclusive, 9,346,661.03 ; on which final proof and entry might have been made in 1888 or earlier.

Total number of acres on which final proof was made, 784,037,23, or 8.4 per cent. of possible number.

Total number of acres planted, 784.037 ÷ 16 = 49.002.

Total number of trees declared to have been planted and cultivated, 38,076,350, or less than one tree for each acre entered for timber culture.

APPENDIX C.

SOUTHERN CALIFORNIA.

"This portion of California is divided by parallel ranges of mountains, which here and there coalesce and become a confused mass of peaks. Between these ranges are valleys of various extent, but all of any agricultural value within 60 or 70 miles of the sea. To the east of the main Sierra Range lie the great deserts of Mojave and Colorado. These are broken by low barren hills devoid of any verdure whatever.

"The rain-fall varies between 25 inches at some points on the sea coast and mountain ranges, to 3 or 4 inches at points on the desert. The desert rain-fall usually occurs in summer. These conditions, as far as the United States are concerned, are peculiar to the Pacific slope. The result of this distribution of the rain-fall makes the use of water for irrigation essential for most crops not maturing in winter or the rainy season, and adds a great value to permanent water supplies for domestic as well as for agricultural puposes.

"The climate in this country is divided into a wet and a dry season. In the wet season it ought to rain but it often does not. In the dry season it ought not to rain but occasionally does.

"*Timber Area.*—Area of timber land in southern quarter of California—an area, say, of 50,000 square miles—timber 1,000 square miles, or one-fiftieth of the whole. This timber is confined almost exclusively to the tops of the mountain ranges, and to an altitude varying between 3,000 and 8,000 feet. There is also a small amount of timber in the narrow cañons which carry the water from the mountains to the valley.

"While the forests of timber trees are thus shown to be very limited in extent, and far below the proportion which has been demonstrated in European countries to be needed for the best productive capacities of a country (about one-quarter), the brush, or chaparral, covers extensive areas in southern California. In Los Angeles County, which is the great agricultural producer of the south, timber trees cover one-twenty-fifth of its area, and are so inaccessibly situated in the mountains as to supply none of the immense demands for lumber of the community. One-third of the total area of the country is in chaparral. This brush-growth is from 2 to 12 feet in height. In some places it is so thick as to be almost impenetrable, while, as we pass to the back ranges and the desert, it becomes so thin and scattered as scarcely to be deemed of importance on the water-sheds.

"San Bernardino County has one-fiftieth of its area in timber, which is sufficiently accessible to be considerably used for local purposes; one-fifth of the area of this county is in brush.

"San Diégo County has about one-fortieth of its area in timber, which is used locally in a small way, and about one-fifth in brush.

"The other counties composing the district have a somewhat smaller proportion of covering of forest and brush.

"The chaparral throughout the entire area is confined to the mountains and foothills.

"On the western and southern slopes of the first important ranges from the ocean it is densest. As we go back towards the desert the brush-covering decreases in density, until, on the desert itself, all the ranges are perfectly bare. The natural covering, as it now exists, is a reliable indication of the extent of the rain-fall, modified to some extent, perhaps, by the exposure of the mountain-growth. That on the northern, or shaded side, is proportionately greater than that on the southern.

"*Effects of deforestation.*—On the other hand, extensive areas of brush land have been denuded by fire, and some waste in this way has taken place among the timber trees. These have also been much thinned out in the localities named, from which lumber is being taken. The effects of this destruction of brush and timber have been plainly appreciable in every case.

"There have been two effects which have followed the destruction of the brush or forests on the mountains of this district. The first—production of torrential action from such denuded water-sheds. Great numbers of these cases have been noted, where the rain-fall has been delivered with suddenness and with great volume, together with a large amount of débris, sand, bowlders, and gravel, from burned-off places. The results have been disastrous, sometimes in a small and sometimes in a large way, according to the area denuded. Some lands have been cut and gullied, others have been covered with dèbris and injured in this way. A number of orchards and other agricultural lands in the San Gabriel Valley have become the beds of torrents, owing to the destruction of brush on the foot-hills of the Sierra Madre Range.

"The second effect of the destruction of the mountain covering, and the consequent rapid discharge of the rain-water, has been the diminution and sometimes entire drying up of the springs and streams coming from injured water-sheds. The most notable cases of these results, easy of access and examination, are as follows:

"Fire on the Mission Cañon water-shed at Santa Barbara; subsequent destruction of the company's works situated in said cañon, and diminution of summer flow of water.

"Fire in Tejunga Cañon; subsequent injury to lands of E. L. Wicks by flood and cutting, and probable augmentation of damage by great flood of Los Angeles City in 1882 and 1883.

"Fire on the water-sheds of Soledad Cañon; subsequent destruction of bee ranches by flood, and of roadway and property of Southern Pacific Railroad. The damage to this railroad involved an interruption of travel for nearly six weeks, and in the neighborhood of $1,000,000 in money. This fire was set by stock-herders, nominally to benefit pasture.

"Edwards' fire on Precipice Cañon water-shed; subsequent diminution of summer water supply from this cañon. Destruction of brush on foot-hills on Sierra Madre Mountains near Pasadena; subsequent appearance of two torrents, which have continued to do great damage to orchards, agricultural lands, etc.

"Fires on Santa Anita, San Gabriel, Sawpit, San Dimas, and San Antonio Cañons, and in many other localities, with similar results.

"The destruction of small wood at Los Coyotes Ranch; subsequent disappearance of spring in said locality.

"For further detailed accounts see page 27, First Biennial Report of California State Board of Forestry.

"Notice may be called, in a general way, to the fact that where the rain-fall is the heaviest—say 25 inches on the steep chaparral-covered Sierra Madre Range—floods have done no damage except from burned water-sheds; while from the bare hills of the Colorado Desert, with a rain-fall of 4 or 5 inches, extensive damage is done every year or two to the only thing there to damage—the road-bed of the railway.

"The consideration of these facts makes it apparent that the brush and forest mountain lands of southern California of no direct value to agriculture, are of great indirect value to every industry in that section.

"*Extent and effect of Tree-planting.*—Tree-planting throughout this area has been carried on to a considerable extent. It has, however, been limited to the fertile valleys upon the western water-shed. In a few places on the edge of the desert, but where water has been brought down, as at Riverside, San Jacinto, Antelope Valley, etc., considerable areas have been planted to fruit trees, with forest trees as wind-breaks to protect them.

"The effect of this tree-planting has been to diminish the force of the winds. The orchards planted along the edge of the Sierra and cultivated area, planted up to and during 1880, suffered a great deal from the hot dry desert winds. I have seen the bark of the trees and the fruit frequently excoriated by the sand carried by the wind, so that the tree and fruit gave the appearance of having been subjected, on the windward side, to a sand blast. Since 1882 I have not known of anything of this kind on the westward side of the mountains.

"Another effect of the plantations has been to diminish the efficiency of the wind-mills—at Riverside, for instance,—which is a colony reclaimed from the desert and now shipping about 2,000 car-loads of product annually, the domestic water being taken by wind-mills from deep wells. When the colony was first started the wind-mills set up to pump this water did more work than was necessary. I am informed now, by some of my friends having orchards at this point, that they experienced the greatest difficulty in getting from their wind-mills a sufficient supply of water.

"The hot desert winds have been undoubtedly lessened in force in our valleys, and so also have what we call trade winds.

"This trade-wind is one which blows in the dry season from the ocean towards the desert. In some places it blew very strongly, so much so as to stunt and disfigure trees subjected to it. One of these places was the Santa Maria Valley. The settlers in this locality have planted wind-breaks of great extent, with the effect of doing away with the damage of this wind. The only place where forest culture has been undertaken to any considerable extent is in Los Angeles County. Several large plantations have been made here with a good profit to the experimenters. There has, however, been no sufficient forest work, in the proper sense of the word, to modify anything, except in a very local way.

"*Recommendations.*—A forest policy should be inaugurated to maintain the integrity of the forest-covering for the purpose of preventing the formation of torrents or destructive floods, and the protection of the permanent water supplies of the country.

"Wherever the desert lands have been brought under water; that is, had water brought so that they could be irrigated, as at the great and productive colony of Riverside, they have proved very fertile. If the policy be adopted by the Government of making valuable and habitable vast extents of the Mojave and Colorado Deserts by irrigation, the storage of water for this purpose would necessarily be in the high ranges receiving considerable rain-fall. If the brush covering, or forests, be burned or destroyed on the water-shede furnishing the supply of such reservoirs, the unimpeded rain-fall flowing off more rapidly must carry great quantities of débris, sand, gravel, etc., which will destroy the efficiency and value of the reservoirs by filling them up. Consequently, co-incident with the adoption of such a policy, a rational forestry system should be inaugurated." (Abbot Kinney.)

Mr. Fernon also called attention to the annual report for 1889 of the forestry division on "The Forest Conditions of the Rocky Mountains," etc. He filed a printed copy of the same. It is already printed for the Department of Agriculture.

STATEMENT OF C. V. RILEY, ENTOMOLOGIST DEPARTMENT OF AGRICULTURE.

The CHAIRMAN. Please state your position.

Mr. RILEY. I am Entomologist of the Department of Agriculture.

The CHAIRMAN. On what subject is the paper which you submit?

Mr. RILEY. On the general subject of the importance of extending any system that may be adopted of irrigation from the entomological stand-point; that is, with the view of checking the ravages of some of those insect pests that do so much damage in the West, particularly the Rocky Mountain locust, or so-called grasshopper, and chinch-bug.

As these matters have been published and the recommendations of the Entomological Commission, which had the study of the grasshopper question in charge, are on record, I have referred to those recommendations. I will only say in a few words that there is nothing concrete to say to you except this, that we dealt with the Northwestern region. Practically these facts stand out boldly, that the native home of that grievous pest is this extreme Northwest region, the permanent breeding ground of that insect.

The only way in which it will be possible in time to overcome this pest is by an extension of settlement. The mode of irrigation that will enable you to extend your settlements is the mode I believe to be the feasible mode. So far as this country is concerned, we have simply suggested some system which must be taken up by the Government, because it is beyond the power of private enterprise—some system that will enable you to save in reservoirs the immense waste of waters from the chief arteries, like the Missouri, and the waste that comes from the overflow system, by building reservoirs that shall hold it.

The CHAIRMAN. We have considered that subject very much, but after we shall have accomplished all that we can accomplish in regulating the irrigation of the arid lands there will be a large area of land above the lines of the ditches that will be liable to be the breeding ground still of those insects.

Mr. RILEY. What is called the permanent region, which is essentially the arid region, trenches upon the subarid region. I have not the time, even if I had the ability, to discuss the points that should be brought up for consideration before you as to what the irrigation system should be. It should of course embrace the underground currents as well as others.

We made a suggestion ten years ago—now somewhat antiquated perhaps—which was that the Government should donate a strip of land running from the Black Hills to the northwest line—right to the boundary—to any company that would undertake to develop a system of irrigation and improvement; believing that that region once thoroughly developed, these pests would be got rid of. If you can retain sufficient water to enable you to cultivate trees or any other crop in this settlement you would at once solve the question of the vast devastating swarms of grasshoppers.

I believe that Government aid should come in only where private enterprise will end. In all valleys which give promise of development I think we can depend on private enterprise developing as much as possible; but Government aid should come in when that will end.

That is why I think Government service should consist largely, as has been well said, of locating possible reservoirs, indicating what they will cost and availing ourselves of the large bodies of water that are annually sent into the sea during the high tide seasons.

The CHAIRMAN. Then your idea is that as the country west of the great plains is developed and brought into cultivation the home of the grasshopper will be limited gradually or cease to exist?

Mr. RILEY. Without question, in proportion as settlements extend. Anything that will permit settlers to live and cultivate the soil, in proportion as that settlement encroaches on the arid land we shall have less and less of those grievous periodical devastations of the grasshopper.

Mr. Riley submitted the following:

REPORT TO THE SECRETARY BY THE DIVISION OF ENTOMOLOGY IN REPLY TO INQUIRIES OF THE COMMITTEE.

The question of the proposed reclamation of the arid lands of the West by irrigation is of great importance from the entomological stand-point, and particularly in view of its influence upon the destructive appearances of the Rocky Mountain locust, or Western grasshopper, which at irregular intervals has greatly damaged the agriculture of certain of our Western States and Territories. The last important invasion of this pest occurred during the years 1874, 1875, and 1876, and the devastation which it occasioned at that time is so fresh in the minds of all as to require no elaboration of the importance of the subject. The reports of the United States Entomological Commission, an organization founded in March, 1877, and composed of Profs. C. V. Riley, A. S. Packard, and Cyrus Thomas, consider the question of the influence of irrigation of a large extent of the arid territory upon the increase of this pest, and from the first report of this Commission, published during the year 1878, and the second report, published in 1880, can be drawn a complete summary of the writings on this subject and the views in full of the Commission. Copies of these reports would accompany this statement, but they have been long out of print. They may be found, however, in the library of the Geological Survey.

One of the important results arrived at is the conclusion that an extensive system of irrigation upon a scale of greater magnitude than any which can be undertaken by a pioneer population will be not only necessary to the carrying on of agricultural operations within the belt of territory mapped out as the permanent breeding ground of the locust, but that the prime result of such an introduction of diversified agriculture into these regions will be the abolishing of the conditions necessary to a permanent reproduction of the species, and a consequent reduction to a minimum of the danger of the appearance of destructive migratory swarms. The one fact, that according to the careful statistics gathered by the Commission the loss from this pest during the years 1874 to 1877 amounted to upwards of $200,000,000, is a mighty argument for the expenditure of the sums which it is proposed to devote to the purpose which Senator Stewart's committee has now under investigation. The words which follow are quoted from the first report above referred to:

"It is evident, therefore, that the final and complete solution of the locust problem depends to a certain extent upon the possibility of modifying, to some degree at least, the aridity of the great plains of the Northwest, which undoubtedly form the native breeding grounds of these insects.

"By most persons this will be considered equivalent to saying that the locust problem will never be solved. It would scarcely be proper for us here to enter into a discussion of the question of the possibility of modifying the condition of the dry area, but we can not refrain from placing upon record our protest against any such conclusion as this. That man, with a mind that can bring art, science, and mechanics to the perfection now visible on every hand, must be forever unable to convert the desert into fertile fields or to redeem the waste places of earth we can not believe, unless we are shown that the moisture which once supplied these areas has forever taken its departure from our globe.

"To what extent these dry areas of the West can be supplied with water and rendered fertile must be determined by those who are proficient in this particular branch of science; but that large sections can be redeemed by proper efforts, if made on a scale of sufficient magnitude, we have no doubt.

"By utilizing all the water that flows down from the mountains for the purposes of irrigation; by collecting in reservoirs the winter supply and distributing it in the growing season, a very large section of these plains might be brought under cultivation, and extensive forests grown where now the surface is naked and barren. Every field brought into cultivation, every grove planted, is just so far a step toward the ultimate solution of the locust problem; and the nearer these can be brought to their native home the more effectual will they be in rooting them out. If extensive efforts in this direction were made in British America, north of Montana, also in eastern Montana, western Dakota, and the regions around the Black Hills, it would not only be of immense benefit in supplying new agricultural fields for emigrants but solve the locust problem. It would also be a most effectual method of settling the Indian question in this region. Just what can be done in the way of redeeming these areas we can not say, but when their settlement depends upon it, and the welfare of a much larger area south and west also depends upon it, certainly the question is worthy of consideration by our national authorities.

"The day is not far distant when our National Government will be compelled to meet this important question and to test the ability of man to accomplish the work.

"The progress of settlement westward must necessarily be slow when it, as is now beginning to be the case, impinges upon the sterile area; it can only push onward when the front line is backed by a dense population and farms studded with groves. It is possible that if there were no other impediments to overcome than this sterility, formidable as it is, the gradual filling up of the border area with an active population would modify the conditions sufficiently, at least, to allow the pushing into and redemption of a belt of considerable breadth. But when to this difficulty is added the devouring locust the hope of success is greatly diminished." (First Report U. S. Entomological Commission, pp. 126–127.)

Further quotations from this and the second and third reports of the Commission are appended and should be studied to enable a full understanding of the probable influence of such a course as the Commission has recommended. The desirability of forest planting is frequently mentioned in these extracts and the influence of such a move in altering for the better the conditions of the permanent breeding grounds of the locust can not be overestimated.

The effect of irrigation upon the Rocky Mountain locust dwarfs into comparative insignificance anything which may be said concerning its influence on other destructive species, yet there are many forms which depend for their existence and multiplication upon a dry climate and which a thorough system of irrigation would render comparatively harmless.

This has been recognized by the prominent writers upon economic entomology, and I may quote the words of my chief, Professor Riley, as follows:

"I have repeatedly laid stress in my writings on the importance of irrigation in combating several of our worst insect enemies, and aside from its benefits in this direction every recurrence of a droughty year convinces me of its importance as a means of guarding against failure of crops from excessive drought. I am glad to know that many farmers, and especially small fruit-growers in the vicinity of New York, are preparing in one way or another for irrigation whenever it becomes necessary, and I was pleased to hear Dr. Hexamer, at the late meeting of the American Pomological Society, urge a general system of irrigation as the most profitable investment the cultivator can make in a climate subject to such periods of drought as ours is known to be."

Perhaps the most striking example among this class of insects is the chinch-bug—a species which damages certain cereal crops to the extent of upwards of $50,000,000 in years of abundance. This insect is directly influenced by moisture and seldom occurs in numbers in the more eastern States, except after two or more successive seasons of drought. After a year of successive multiplication these insects will often be found to have hibernated in immense numbers, and it is a well known fact that heavy rainfall the succeeding spring will destroy them almost completely. This being the case, the artificial system of irrigation will enable the agriculturist to hold this insect completely in check, and such a system as it is proposed to introduce in the West will render the grain-growers of the reclaimed regions independent of the damage which may be done by this insect and will enable them to compete on most advantageous terms with the grain-growers of the more eastern localities whose crops are occasionally subject to almost total loss by this insect enemy. I again quote from Professor Riley:

"Irrigation, where it can be applied—and it can be in much of the territory in the vicinity of the Rocky Mountains where the insect commits sad havoc, as with a little effort in many regions in the heart of the Mississippi Valley—is the only real available practical remedy after the bugs have commenced multiplying in the spring. I wish to lay particular stress upon this matter of irrigation, believing as I do that it is an effectual remedy against this pest, and that by overflowing a grain field for a couple of days or by saturating the ground after as many more in the month of May, we may effectually prevent its subsequent injuries." (Seventh Rept. Ins. Mo.)

We may mention also the case of the grape-vine phylloxera and may again quote from Professor Riley:

"Submersion, where practicable, and where it is total and sufficiently prolonged is a perfect remedy. This is what even the closest student might expect, as he finds that excessive moisture is very disastrous to the lice. M. Louis Faucon, of Graveson (Bouche du Rhône), France, has abundantly proved its efficacy, and has, by means of it, totally annihilated the insect in his vineyard which was suffering from it four years ago. From his experience we may draw the following conclusions:

"(1) The best season to submerge is in autumn (September and October, when the lice are yet active and the vines have ceased growing. Submergence for twenty-five to thirty days at this season will generally rout the lice. (2) A submergence of forty to fifty days, in winter, is required, and even where the water is allowed to remain during the whole season, the vineyard does not suffer. (I should consider this very doubtful.) (3) A vineyard should never be inundated for a longer period than two days in summer, or during growth; and though these brief inundations at that season affect only the few lice near the surface, and are by no means essential, they are nevertheless important auxiliaries to the more thorough fall or winter submersion, as they destroy the few lice which are always invading a vineyard in infested districts. These summer inundations will be necessary only after the winged insects begin to appear; and three or four, each lasting less than two days, made between the middle of July and the fall of the leaf, will effect the end desired. (4) An embankment should be made around the vineyard in order that the water may evaporate and permeate the earth, but not run off and carry away any nutritive properties of the soil.

"The varied success which has attended the different attempts to rout the enemy by inundation, is owing to the lack of thoroughness in many of them. The ground must be thoroughly soaked for a sufficient length of time. Temporary irrigation does not accomplish the end for the reason that it does not reach all the lice, and does not break up the numerous air bubbles which form in the soil and prevent the drowning of many of the insects." (Sixth Rept. Ins. Mo.)

Too much in fact can not be said of the advantages of a system of irrigation in fighting many insect pests. A good instance occurred in our experience in the spring of 1879 when the Army worm appeared in great force upon a large grass plantation near Portsmouth, Va. The plantation was divided into sections by irrigating ditches and it was only necessary to turn on the water to isolate a badly infested section and to devote it by rolling, fire, or some other means of destruction preventing ready spread of worms to other sections. In the same way rice planters have a ready means of fighting insect pests at hand.

Other insects might be particularized, but the general statement that from the stand-point of the economic entomologist irrigation in general is a great help in fighting insect pests, and from the marked illustration of the great good to be accomplished by the reclamation of the arid regions in connection with the damage done by the Rocky Mountain locust, it will probably be considered that further elaboration will be unnecessary.

Respectfully submitted, May 13, 1889.

L. O. HOWARD,
Acting Entomologist

EXTRACTS FROM THE REPORTS OF THE UNITED STATES ENTOMOLOGICAL COMMISSION.

In the permanent region which embraces the Rocky Mountain plateau and the bordering plains from the middle of Colorado northward the rain-fall is insufficient for agricultural purposes, and hence irrigation has to be resorted to. In the temporary region this is unnecessary. The plains and plateaus of the permanent region are to a large extent distinguished by the presence of *Artemisia*, Chenopodiaceous plants, and what is usually termed "bunch-grass;" in short, by all the characteristics of a drier climate. One other peculiarity which should not be overlooked appears to mark roughly the southern boundary of the permanent home of the Rocky Mountain locust, and that is the isothermal curve or line of the fiftieth degree of mean annual temperature, which also corresponds very nearly with the isothermal curve or line of summer temperature of seventy degrees. But this applies only to that portion of the region which extends upon the plains east of the mountains.

If any practical means of exterminating the locusts in this permanent region could be devised the whole locust problem could be solved, and nothing further would be necessary. But when we take into consideration the vast extent of this area, and the fact that a very large portion of it can not be brought under cultivation without a material change in the climatic conditions, there appears but little hope that such a means of actual extermination will ever be devised, however much we may hope to check the injurious increase of the pest by the means recommended in the concluding chapter of this report. Our discussion of the future prospects of this region in reference to agriculture may as well, therefore, proceed on this basis. (Second Report United States Entomological Commission, pp. 15–16.)

* * * * * * *

A careful investigation of this subject for several years and repeated visits in person to this region have served to convince us that, with the advantages afforded by the system of irrigation necessarily adopted, there is no reason why the agricultural area lying along the east flank of the range should suffer any more from these pests than portions of the temporary regions. (*Ibid.*, p. 19.)

* * * * * * *

This agricultural belt, extending from Colorado into British America, is partly along the margin of and partly in the very heart of the permanent breeding-grounds where the swarms that invade the temporary region originate. It follows, then, as a natural consequence, that just so far as the numbers are lessened by the operations in this section, just so far will the agriculturists of the temporary region be benefited, and, as we will hereafter see, like operations in the latter region will benefit those in the permanent region. We are fully aware of the fact that the part of this vast region which can be irrigated and cultivated is small in comparison with the whole area which forms the native home of the species, but, fortunately, in one respect this cultivated belt occupies in part, at least, the point of departure of the swarms which invade the temporary region. This fact, therefore, renders it more important that it be occupied by an agricultural population.

Although we have admitted that we are unable to present any plan of exterminating the locusts that holds out sufficient promise of success to justify the General Government in undertaking it, it does not necessarily follow that there is no plan of modifying the evil which the Government would not be justified in undertaking. On the contrary, if the views we have advanced be correct, they suggest a means by which the General Government might greatly aid in bringing about the desired result; and, fortunately, the result would be beneficial even should we be mistaken in the opinions advanced.

As will be seen by what has been stated, the great desideratum is to settle the cultivable belt alluded to as rapidly as possible with an agricultural population. Wherever valuable and permanent mines are discovered in the neighboring mountains, the arable areas in the vicinity will be taken up and cultivated to an extent at least sufficient to supply the demand for agricultural products, as in parts of Colorado. But there are large sections where no such influence will be brought to bear, and this is the case along that portion of the belt where the agricultural population is most needed for the purpose mentioned.

An examination of map No. 1, in our first report, will show that a comparatively limited belt in central Montana, extending from the Big Horn Mountains northwest to the British line, a little west of Cypress Hill, forms the turning-point of the locust movements. Without now repeating the data which may be found in that report, we may summarize it by saying that from this region a large portion of the swarms come which visit Dakota, Minnesota, Nebraska, and Kansas; from this area also proceed a large portion of the swarms that move southwest into Idaho and Utah. This appears to be the point to which most of the returning swarms from the temporary region direct their flight.

That there are other areas in the permanent region which appear to be special breeding-grounds, as points of departure, is certainly true, but none to such an extent as this, and none affecting an agricultural area bearing any comparison with the area affected by the locust swarms originating in this belt.

Even should it be shown by subsequent investigations that as a rule the swarms falling on the temporary regions come from intermediate points, as central and southern Dakota and northwestern Nebraska, the facts already ascertained warrant us in asserting that, as a very general rule, they originate in the belt mentioned.

It is evident, therefore, that if any method can be devised by which an agricultural (not pastoral) population can be thrown into this belt, it will form one of the best possible means of modifying the evil. If they can be effectually distributed in this area the result will be of immense value to the agricultural interests of Dakota, Minnesota, Nebraska, Iowa, and Kansas, in fact of the entire temporary region. We do not pretend that it will wholly relieve this area from locust invasions, but it will very materially lessen their extent and injury.

In order to carry on agricultural operations to any great extent in this belt, an extensive system of irrigation will be absolutely necessary. It will have to be on a scale of greater magnitude than any that will be undertaken by a pioneer population. We doubt the propriety of the General Government undertaking such a work directly, if it is possible to accomplish it in any other way. This, we think, may possibly be done by giving the land for this purpose. We are fully aware of the opposition at present to the Government's donating any more of the public land, but the circumstances of this case bring it out of the general rule. If donating the entire body of public land, in the belt described would suffice to settle it with an agricultural population, not only would the very purpose for which it is held be accomplished, but, if our views are correct, the result would be of immense benefit to the border States.

We therefore suggest the following as probably the most feasible plan of accomplishing the desired end: Let the United States donate a belt of 50 or 60 miles in width, running from the Black Hills west-northwest, so as to strike the Yellowstone River a short distance above the mouth of the Big Horn River; from thence northnorthwest, by way of Fort Shaw or the mouth of Sun River, in the direction of Fort Hamilton, in British America; this to be granted on condition that the company to which said land is granted shall, within a given time, construct a railroad from the Black Hills along the line designated, to the international boundary, shall undertake and carry out, to an extent to be designated, a system of irrigation, and shall equip and keep in operation said road for a certain number of years.

Whether such grant will be sufficient inducement for any competent company to undertake the work specified is probably the chief difficulty in the way of successfully carrying out this plan. On this point we do not feel qualified to express an opinion. That such a road, starting from the Black Hills, if once built, would soon be connected southward and eastward with other roads, can not be doubted. That it would be the best possible means of bringing an agricultural population into this belt can not be doubted. It would also be an important factor in settling the troublesome Indian problem in this section of the West.

If the plan should be adopted it might be well to colonize, if possible, with Russian peasants who are accustomed to fighting locusts.

The advantage to be derived from this plan consists chiefly in the fact that it is possible to destroy the young to a very large extent by the use of the proper means. If this is done in the very heart of their breeding-grounds, it greatly lessens the numbers that will migrate. Not only does it prevent the number destroyed from migrating, but for each one killed, so to speak, an entire family brood of the next or migrating generation is destroyed. In other words, the destruction of thousands there would be as effectual as destroying millions of the migrating swarms. The means of destroying the young, as before stated, can be made more effectual in the sections where irrigation is carried on than where it is not.

As shown in our first report, the destruction of the young locusts bred in the temporary region from the invading hordes not only gives immediate relief, but also tends to postpone future invasions by so lessening the numbers in the returning swarms that a longer time is required for development. With an agricultural population in the area designated, the work of destruction would then be carried on at each end of their migratory route.

Here we may also remark that the present idea of making that section of our country peculiarly pastoral area, while doubtless profitable to the present and for two or three generations to come, will in the end entail hardships upon those to follow. It can no longer be doubted that while the destruction of forests was the chief agency, yet the pastoral habit of the people of Western Asia and other oriental countries, once so fertile but now so barren, was one important factor in producing the present dry and barren condition of those countries. No country in the interior of a continent, unless supplied with numerous lakes or numerous and permanent rivers, can remain permanently fertile and productive if given up largely to pasturage of sheep, goats, and cattle without cultivation. The rapid destruction of mountain forests and pasturing their slopes and bordering plains will most certainly have a tendency to render that portion of our country more dry and barren.

Unless, therefore, our Government adopts some policy by which an agricultural population can be thrown into that area the day will most assuredly come when it will be as barren and desolate as the plains of Arabia. The development of the locusts is but an incident of the change from a former condition of abundant moisture to the present dry one. But this branch of the subject we propose to omit at present.

It will be seen, therefore, by the foregoing that we think it is possible to modify to a very large extent the operations of the locusts so far as these relate to the area along the east flank of the mountains, and that the General Government may, without any very great expense, very greatly assist in the work. (*Ibid.* pp. 19-22.)

* * * * * * *

This certainly shows a very moderate climate for this northern latitude. Wheat, oats, rye, and barley grow well, and Indian corn is also raised without difficulty and produces good crops. Such fruits as apples, plums, cherries, currants, raspberries, and gooseberries may be grown and matured here, the climate presenting no serious obstacles.

The amount of land that can be brought under cultivation depends wholly upon the amount of water that can be obtained for irrigation. If the plan for making reservoirs for preserving the winter supply should ever be adopted, the breadth of the agricultural belt would be very largely increased, and this would be doubly beneficial in assisting to destroy the locusts and tending to increase the moisture in the atmosphere by forming a larger evaporating surface. The growth of trees and shrubbery around these reservoirs would also be beneficial in the same direction.

But experience in the settlement of these mountain regions and Western Territories shows that no such extensive works will, or in fact can be, undertaken by a pioneer agricultural population. Some efficient aid of some kind must be given if such a scheme is ever carried into effect, and if the land itself will do this, the Government will act wisely in giving it for this purpose. (*Ibid.*, p. 23.)

* * * * * * *

As shown by our first report, the region around Salt Lake is subject to repeated locust invasions from the north, apparently the resulting broods of the swarms that originate in that portion of Montana of which we have been speaking, and which, pouring over the mountain pass at the head of Jefferson River, move down Snake River Valley.

If the scheme we have suggested should be carried out and should prove beneficial in reference to the eastern area, it would have, to some extent at least, a like effect as to this section. If it is possible to establish and maintain an agricultural population in the Upper Snake River Valley, this would have a strong tendency to modify the evil. But the present barren aspect of this region would seem to forbid any hopes of ever accomplishing this desired end. Still there appears to be one possible means of bringing this about, at least to a limited extent. The demand of trade will doubtless complete the railroad already started in that direction, which is one step toward the desired end, but something more is required in this case.

Snake River affords a large body of water which, if properly utilized, would irrigate a large breadth of land, and, notwithstanding the barren appearance of the soil, is really fertile when irrigated. It is possible, with a moderate expense, to throw dams across this stream at certain favorable spots, and by this means to spread the water over the adjoining plains. A work of this kind would, of course, have to be done by the General Government. The feasibility of this project could easily be ascertained by an officer of the Engineer Corps of the Army; and as this is on the line of the chief intermontane thoroughfare and also of the locust invasions of this region, the subject is certainly worthy of the attention of the Government.

As will be seen by what we have presented on this subject, the philosophy of our plan for modifying the evil is to place an agricultural population in the very home of the species, which from necessity would be compelled to wage a constant warfare against them.

By stirring the soil their nests would be disturbed; by fighting the young their numbers would be diminished; and as irrigation would be necessary the effect of dry seasons on the crops would not be felt as in the temporary region. The possibility of inundating to a considerable extent their egg deposits by the winter supply of water would tend to diminish their numbers. The fact that their breeding-grounds are chiefly in the limited agricultural areas is also another argument in favor of the plan.

That large areas would be left where locusts breed and pour down on the nearest cultivated areas, as in western Colorado, is certainly true; but this does not lessen the value of the plan proposed, nor is it a reason why it should not be put into operation. (*Ibid.*, pp. 24, 25.)

* * * * * * *

Naturally with the increase in the number of farms and advance of the settlements upon the frontier the devastation by locusts will be felt less. They will divide their ravages among more farmers, and hence none will feel the losses nearly as much as did those who were isolated from their neighbors during past invasions. Thinly-settled districts suffered much more than those which were more thickly settled; and those lying out upon the prairie than those adjoining and interspersed with groves. During these invasions there was no year but in which a portion of the crops was saved and harvested by the farmers of the extreme eastern portion of Nebraska and other sections of country that were comparatively thickly settled, and that were situated near some natural timber-belt and interspersed with planted groves; while, on the contrary, those that were far away from these natural and artificial groves, and thinly settled, were entirely devastated by the hordes of ravenous insects. Hence we are compelled to acknowledge that the settling of a country in which the settlers are tree-planters has a tendency to diminish the ratio of locust injury.

Tree-planting is not only a matter of great importance to the inhabitants of a country like ours in supplying a much-needed material for fuel during our severe winters, when at times it is impossible to obtain coal—either from the failure of a sufficient supply at the mines, or from the impracticability of reaching towns where it can be obtained—but it is also of untold benefit as a moderator of climatic extremes. By planting trees throughout the Temporary Region wherever they will grow, in time the area in which the locust is capable of continuing its existence but two or at most three generations, without having recourse to the arid regions hitherto referred to as the permanent breeding-grounds, will be increased. Aside from the greater amount of humidity that would naturally follow tree-planting, the spread of locust-feeding birds would be correspondingly increased, and the amount of good thus accomplished could hardly be estimated. As long, however, as there are no retreats or building places in which these little feathered friends of ours can rear there little ones, we need not look for their aid in fighting insect enemies.

The increase in the number of settlers would also add to the number of individuals to fight the locusts, and hence help to increase the sum total of their dead and to diminish the swarms otherwise remaining to do damage and to increase at the ratio of a hundred-fold. (Third Report U. S. Entomological Commission, pp. 44, 45.)

Mr. WILLITS. Dr. Vesey was to have been here, and he had a statement, too, but I will send the paper up.* Dr. Merriam is here, and I would like the committee to hear from him.

The CHAIRMAN. We will hear from Dr. Merriam.

STATEMENT OF C. HART MERRIAM, ORNITHOLOGIST.

The CHAIRMAN. What is your position?

Mr. MERRIAM. I am chief of Division of Ornithology and Mammalogy of the Department of Agriculture.

I was desired by Secretary Willits to come here and speak of the availability of certain areas of the arid lands for the introduction of certain agricultural crops and certain birds and animals which are injurious or beneficial to mankind.

In the southern part of the arid lands camels have been already introduced. Many years ago the War Department introduced camels in this country, and herds are now supposed to be living in western Texas and in Arizona.

Nothing has been done to utilize them as beasts of burden, but there can be no doubt that enormous good and enormous value would result to the arid land by the proper introduction and domestication of the camels of those regions. The herds now roaming wild over considerable areas in the arid lands could be put to very useful service. Our arid lands extend from the Mexican border to the plains of the Saskatchewan and embrace a number of distinct climates. Each of those climates is adapted to the wants of certain classifications of animal and vegetable life. We find that we are able to subdivide the West into a number of areas which we call life areas, because each of those areas possesses associations of plants and mammals, birds, reptiles, insects, etc., that are not found in continuous areas, and we find in applying agriculture to those areas that the same areas that support definite associations of plants and animals in a wild state are adapted by nature to definite kinds of agricultural crops and to definite breeds of animals.

This is a subject that has been almost entirely overlooked in studying the question of the relation of climatology, particularly of temperature and humidity, to the relations of life; it is one of the utmost importance. I think it is not saying too much to state that agricultural science in this country is going to be completely revolutionized whenever it is studied in connection with the natural life areas and the climatology of the country. Experimental agriculture will cease.

---

* Dr. Vasey's paper was not received.

The **Chairman**. Have you to any considerable extent classified the sections, and the animals belonging to them?

Mr. **Merriam**. I have been engaged in that work for the last four or five years, and have a number of maps now in progress of the whole United States, showing the primary, secondary, and tertiary life areas in which the country is subdivisible. That is the work in which I am now engaged.

The **Chairman**. That would not come within the scope of our report; but I agree with you that it is a very important subject of inquiry, if you can ascertain as to each region when developed what will be the products, and what animals will thrive there, and what will be suitable for them for food. That information will be most valuable to settlers in order to inform them what animals they may keep.

Adjourned.

FIFTH DAY'S SESSION.

Washington, D. C., *March* 13, 1890.

The committee met pursuant to adjournment.

Present: Mr. Stewart (chairman), Mr. Moody, Mr. Casey, Mr. Reagan, and Mr. Jones, of Arkansas.

STATEMENT OF CAPT. C. E. DUTTON, U. S. ARMY, CHIEF ENGINEER U. S. IRRIGATION SURVEY.

The **Chairman**. Captain, you are an officer of the Army?

Captain **Dutton**. I am, sir.

The **Chairman**. And assigned to the Geological Survey?

Captain **Dutton**. Yes, sir.

The **Chairman**. State what connection you have had with the Irrigation Survey, what your position has been in that survey, etc.

Captain **Dutton**. When the survey was first authorized by law Major Powell requested me to take charge of the field-work of the engineering and hydrographic parties. The details of the field-work were drawn up and submitted by myself to the director, and were approved by him, and, since the passage of the law and since the time when the appropriation became available, I have had charge of the engineering and hydrographic work.

The **Chairman**. Has there been any other work than hydrographic and engineering work done in connection with the survey?

Captain **Dutton**. Within the limits of the appropriation?

The **Chairman**. Yes.

Captain **Dutton**. Yes, sir. There has been a large amount of topographic work, with which I have had nothing to do.

The **Chairman**. Of the $350,000 that have been appropriated how much has been expended for hydrographic and engineering work, and how much for topographic work?

Captain **Dutton**. Out of the first appropriation—you will remember there were two——

The **Chairman**. (Interposing.) There were two.

Captain **Dutton**. Out of the first appropriation of $100,000 $36,000 were allotted for the work under my charge.

The **Chairman**. The engineering and hydrographic work?

Captain **Dutton**. Yes, sir; there was a contingent fund reserved for expenditure under the immediate charge of the director, for office expen ses, and for special expenses which could not be foreseen in the original estimates, and also to be a kind of insurance fund against any deviation which might compel us to exceed this allotment or else sacrifice valuable work. The amount of that, I think, was $6,000. The remainder of the $100,000, that is, $58,000, I understand was applied to topography.

The CHAIRMAN. As regards the second appropriation?

Captain DUTTON. As regards the second appropriation, the original allotment to the work under my charge, that is, the engineering and hydrographic work, was $110,000. There was a contingent fund of $20,000, and $120,000 was allotted to the topographic work.

The CHAIRMAN. Has all of that appropriation been expended?

Captain DUTTON. The last appropriation?

The CHAIRMAN. Yes, sir.

Captain DUTTON. No, sir.

The CHAIRMAN. How much has been expended of what was allotted to the hydrographic and engineering work?

Captain DUTTON. I can not give the exact figures, but I can approximate to them off-hand. There still remains available for expenditure about $29,000, reckoning from the 1st of March, for the work under my charge. As regards the work in the topographic branch I am unable to say how much remains unexpended.

The CHAIRMAN. The $29,000 will be expended as you go along, in completing the work?

Captain DUTTON. Yes, sir; to complete the office work, and more especially to keep the hydrographic work going, which it is absolutely necessary to maintain constantly, without any intermission, in the field, that is, to a certain extent. The great bulk of the remainder now unexpended is being applied to the hydrographic work.

Senator REAGAN. That is, the remainder of the $120,000.

Captain DUTTON. The remainder of the $110,000. That is a class of work which requires more constant and steady expenditure than the engineering work, because it is necessary to keep up stations in the field constantly.

The CHAIRMAN. Is there any connection, in practical operations, between the topographic work and the engineering work; how do they co-operate, if at all?

Captain DUTTON. There is a certain amount of general utility for engineering and hydrographic purposes to be found in a good topographic survey. According to my understanding there is no absolute dependence upon topographic work for the proper conduct of good engineering and hydrographic work; in other words, an engineering and hydrographic survey could be conducted with good results, meeting the purposes and requirements of the law, if there were no topographic survey. Our results probably would be in some measure better spread upon the record, better published, and made more intelligible, if we had good topographic work in advance, and good topographic work would undoubtedly be accompanied by certain conveniences; but the question of necessity is one of degree.

Senator REAGAN. I do not understand these things very well. Will you define the difference between what you call engineering and hydrographic work and topographic work, so we can see what the differences between the two classes is?

Captain DUTTON. In order to carry out the purposes of this law, as it has been understood in the survey, and in order to meet all the special requirements of the law, which provides for investigating the extent to which arid lands can be redeemed by irrigation, one of the first things which is necessary to know is the available water supply, and not merely the water supply, but also what the water can do—how much a given quantity of water can do, both in general and in particular—as a general rule and in particular cases. It is therefore necessary to make what we call a hydrographic investigation to know how much water we have at our command. The hydrographic work has been understood to include the measurement of the waters flowing in the streams, and to ascertain the rate or distribution of the flow of streams during different parts of the year, to know when the waters are at a maximum and when at a minimum. It is also necessary to know what we term the "duty" of the water, to know how much land the water can irrigate, and if, as is actually the case, it varies from place to place, to know the causes upon which that variation depends—what influences the duty of the water.

There is one other very important matter in this connection which it is necessary to investigate, and that is the subject of evaporation, which becomes a highly important one in reservoirs, and especially in the largest reservoirs, for reasons that will readily suggest themselves to you. A large reservoir is generally a shallow one, and a very large basin can not under any ordinary circumstances receive a sufficient quantity of water to cause a great rise and fall in that reservoir. Now, if the proportion of evaporation to the amount of available inflow of a reservoir is very large it becomes a very important question to know how much that evaporation is, and there are very many cases where the value of a reservoir will turn upon the ratio which exists between evaporation and inflow. Therefore it is necessary to make an accurate investigation of the rate of evaporation. There is still one other question which we consider—a hydrographic one—which we have not as yet taken up systematically, but have only investigated in one or two localities, and that is the quantity of sediment which the streams transport. That becomes a matter of very great importance in determining the life of a reservoir, how long it will take to fill it. These are practical matters which the hydrographic service is expected to investigate. The engineering survey investigates questions of a different character, but into the investigation of the engineering survey the hydrographic survey enters as an important factor. The engineering survey is required to first investigate the possibilities of diverting water from streams, storing water, and the amount of land which can be irrigated by works of a specific character. I think it will appear quite clearly that if we are to obtain the information as to the amount of land which is susceptible of being irrigated we must have for each locality and each district some definite idea of the kind and the extent of the works which are to irrigate them. Therefore the engineering survey is required to form some definite project of works for the irrigation of each district. Their instructions have been to endeavor to select the best. I can perhaps convey to you that idea more forcibly by reading to you a portion of the instructions which were given early in this investigation to some of the engineers:

> I desire herewith to place before you certain governing considerations of a general character with reference to the surveys you are expected to make and to the results you are expected to accomplish. In each hydrographic basin it is desired to take the problem; what are the available sources of water supply, and by what means the water may be most fully utilized? A hydrographic basin may mean the water-shed of a large stream or of a small one, or a great river or one of its tributaries; but whether it means a trunk stream or a branch of it (a question to be decided by the engineer), it is assumed that there is some form of development and construction of the work

> which may be judged to be the best that the engineer can devise. The engineers should take no account of works which are already constructed; nor should their judgment be swayed by any opinion on their part as to what works private enterprises and capital are likely to undertake in the next few years. They should rather address themselves to the question already propounded; what is the best system, the one which will utilize the greatest amount of water and produce the greatest amount of irrigation? It is not forgotten that as a practical matter irrigation development in each district starts with a small beginning, with works proportional to that beginning; that it advances through successive stages, by more costly works superseding the primitive ones. But of these the engineer should take no account. His project should embrace what is in his judgment the best system, irrespective of what is or actually may be constructed. At the same time his project should be a practical one, involving no extravagances of engineering, nor transcending the possibilities of attainment, or of maintenance after attainment. The plans should also have a certain unity, and should contemplate a single system of works for each irrigation district. If both reservoirs and canals are required, the reservoirs should be, if possible, projected as adjuncts of the canals. No doubt it will happen sometimes that the rivers alone are more than sufficient for the available land, as in the northernmost States and Territories, or that reservoirs alone are possible, as in parts of the southernmost Territories; but still, even in such cases, unity of plan should, so far as practicable, be kept in view. Engineers should seek to minimize the extension of their projects of distributive works by which water is taken from canals and reservoirs and put upon the land. With a given high line canal it will generally be possible to propose many ways of distributing its water, but the distributive system will in other cases probably be of a distinctive character, forming a vital part of the entire project, and its development in the project will then be necessary.

This instruction was deemed necessary in order to meet the requirements of the law for investigating the extent to which the arid lands are capable of being redeemed by irrigation.

Senator Reagan. You have stated that there would be some convenience in a topographic survey. Is not a topographic survey to some extent indispensable to this work in ascertaining the altitude of the place where you locate your reservoir, the relative altitude of the ground to be irrigated, and to run the lines of the canal?

Captain Dutton. Yes, sir; to know the line of the canal it is necessary to have an exceedingly minute and very carefully detailed topographic survey on a very large scale. It is also very necessary to have a thorough-going survey of the reservoir site itself, and most particularly of the dam site. For this purpose a topographic survey is an absolute necessity; but in speaking I had reference to a more general topographic survey of the whole country. A topographic survey to show the lines of a canal would have to be made upon a scale never less than 1,000 feet to the inch, and is more frequently 100 or 200 feet to the inch, whereas a general topographic map of the very largest size means a survey upon a scale of about 10,000 feet to the inch; that is, our scale for engineering purposes would have to be ten, fifty, or even one hundred times as large as that of a general topographic map. And there is another point in that connection. The most important feature of an engineering survey for engineering purposes deals with the vertical element; that is, with altitudes. The horizontal elements, although important, are far less so than the vertical elements. Now, it would be impracticable to construct a topographic map, at a reasonable cost, with a degree of accuracy at all commensurate with the accuracy which is demanded by the engineering surveys of a canal, or even of a reservoir.

Senator Reagan. Is not such a topographic survey as is being made in the country where you have been a very great convenience to the engineers when they come to arrange the details of the hydraulic part of the work?

Captain Dutton. Yes, sir; it is a convenience; there is no question about that.

Senator **REAGAN**. And it is of great convenience in considering the engineering problems?

Captain **DUTTON**. It is a great convenience. I notice that all my engineers are calling very largely for maps, and the best maps they can get.

Senator **REAGAN**. Are you advised as to the extent to which the topographic surveys have been made and how near they are to completion throughout that Western country generally?

Captain **DUTTON**. Yes, sir; I have a pretty good knowledge of that subject. I know where they have been made and I know their general character.

Senator **REAGAN**. State to the committee about the extent of those surveys.

The **CHAIRMAN**. And also state their general character.

Captain **DUTTON**. Well, sir, you are aware that topographic surveys of various qualities have been going on the Western country for twenty years. They have been made by different organizations of the Government. Some have been made with much more care and much more skill than others. A very large portion of the West has already been so surveyed. There has been a topographic survey made of that portion of the State of Colorado which lies west of Denver. The entire portion of the State west of Denver was surveyed under Dr. Hayden. There has been a very large portion of New Mexico surveyed, by what we are in the habit of calling a mere reconnaissance survey, under Captain Wheeler, of the Engineers. It is on a much smaller scale and much more hurriedly done than a topographic survey, and it has but little of the vertical element in it. We do not consider it a topographic survey. But some portions of New Mexico have been surveyed by the Geological Survey, perhaps about one fourth of the Territory. Nearly one-half of Arizona has been surveyed by the Geological Survey, that, however, being the northern portion of the Territory. About two-thirds to three-fourths of Utah has been surveyed by the Geological Survey. The Wheeler survey made extensive surveys in Nevada, while the Geological Survey has made none there except in the extreme western portion of the State. The Wheeler survey has made very extensive surveys in California, and the Geological Survey has followed them up with their topographic survey, which now embraces about one-fourth, perhaps one-third, of the State—a very fine map. Southwestern Oregon has been surveyed by the Geological Survey, but probably not more than one-eighth or one-tenth of the State has been surveyed.

No surveys of any kind have been made in Washington, and the Geological Survey has made no surveys in Idaho until within the last year, and very few surveys of any kind have been made there excepting in the southeasternmost portion. In Montana a survey was made by the Northern Pacific Railway, known as the Transcontinental Survey, embracing a belt of territory which was adjacent to the Northern Pacific Railroad, mostly within the limits of its land grant, and other portions have within the last three or four years been under survey by the Geological Survey. Perhaps one-fifth or one-sixth part of Montana has been surveyed. In Wyoming there has been very little topographic work done, although a survey was begun there by Dr. Hayden during the last few years of the existence of his own survey, but only a small amount of progress had been made upon it. In the States and Territories east of the one hundredth meridian, within the arid belt, the Geological Survey has been making surveys in the valley of the Arkansas River, and still more extensive ones in the eastern portion of Kansas. It has also been making some extensive surveys in central Texas, gradually expanding its work there. That carries us into the humid region, and there has been a great deal of surveying done, of course, in the Mississippi Valley.

The CHAIRMAN. Suppose a corps of engineers, having a report of the hydrographic work, so that they would have an approximate knowledge of the precipitation and evaporation, and the amount of water flowing in a stream, should go into a valley to locate a reservoir and the lines of ditches for the purpose of conveying the water to such lands as could be irrigated, how much information could they obtain from any topographical map that has been made of any portion of the country? Would they be able to rely on such a map, or would it be necessary for them to do their own work independent of that?

Captain DUTTON. The most valuable information they would get from a general topographic map would be a more accurate means of computing the area of the different water-sheds. I know of no other purpose which would be an indispensable one which would be served by such a map as that. But it becomes a matter of very grave moment to know what the water-shed is. It can be very readily ascertained by a few days' labor, or, if it is a large one, by a labor of a week or two; but as a general rule the exactions of accuracy in the size of a water-shed are not so great but what they can be made fairly and with a sufficient degree of approximation by existing data.

Senator JONES. Why do you have to know the area of a water-shed?

Captain DUTTON. In order to form some judgment in advance of the amount of water which is likely to run off from it in flood-time.

Senator JONES. Then you rely on the area of the water-shed and the average rain-fall to make your hydrographic examinations; or do you measure the streams for the purpose of making your estimates?

Captain DUTTON. Both.

Senator JONES. You do not rely on either one, absolutely?

Captain DUTTON. We place our main reliance upon stream-gauging.

Senator JONES. That is much less expensive than the other?

Captain DUTTON. No, sir; far more expensive. Stream-gauging is very expensive work.

Senator JONES. Is it more expensive than a topographic survey in ascertaining rain-fall?

Captain DUTTON. Oh, no, sir.

Senator JONES. That is the question I asked.

The CHAIRMAN. The captain meant sufficient topographic work to ascertain the area of the water-shed. That amount of topographic work would not cost as much as the topographic work.

Captain DUTTON. I think I can get a rough approximation of almost any water-shed from existing maps.

Senator JONES. Is that sufficient for practical purposes?

Captain DUTTON. Yes, sir.

The CHAIRMAN. Then there is another thing which, it seems to me, you would want to know in planning for a dam. You would not only want to know the amount of water that would come down in flood-times, approximately, but you would want to know the declivities of the water-shed, to determine how rapidly it might come down.

Captain DUTTON. Yes, sir.

The CHAIRMAN. Could the engineers in the field also make allowance for the declivities of the water-shed and judge of the probabilities of strain upon the dam, so as to make allowance for it?

Captain DUTTON. They could get some light upon that subject——

The CHAIRMAN (interposing). Would a topographic map give you some light?

Captain DUTTON. Yes, sir.

Senator JONES. Is it indispensable?

Captain DUTTON. It is not indispensable.

The CHAIRMAN. When they were making the survey could they take the altitude with sufficient accuracy to form a reasonable judgment of it?

Captain DUTTON. Yes, sir. We have no difficulty in getting altitudes in a few hours, or in a day or two at the farthest, with all the accuracy that topographers get it, because the country is now so completely covered with railroads. Topographers are obliged to rely on the railroads as a starting point for their data, and engineers can do that as well as topographers. If a case arises where the locality is very remote from a railroad he can get his altitude in precisely the same way the topographer gets his, that is, by a mercurial barometer. That is a rough way, but it gives the altitude with a fairly satisfactory degree of approximation.

Senator JONES. How long a system of observation does it require in the basin of a stream to determine the minimum water-fall and the maximum water-fall; I mean for practical purposes?

Captain DUTTON. It takes a great many years, Senator. Hydrographic observations once begun should be conducted without intermission for a long period of years, and I think that as soon as practicable the States themselves, or possibly the irrigation districts, should have that business gradually turned over to them and devolved upon them. It is their business, their province. Sooner or later all the irrigation must come——

Senator JONES (interposing). What do you think was the cause of the accident in Arizona the other day?

Captain DUTTON. An insufficient waste-weir.

Senator JONES. That is not the point I had in mind. What was the cause of the engineer making that mistake? I assume that he was competent, that he knew his business, that he knew the size of waste-weir necessary to carry off the water; but it seems that more water came down than he calculated on. Now, no matter if he had been gauging that for a long while, he could not, of course, know how much water would come down in an excessive flood unless a flood came during his observations. The question is whether you can arrive at such information by observations of the flow of the stream as to enable you to reasonably guard against accidents to works of this character, or whether it is necessary to have an examination of the country and know the area drained and the steepness of the water-shed, the amount of water that falls in an average year, and all that—whether that would be a more accurate way of guarding against destruction from floods than to depend on the gauging of the streams.

Captain DUTTON. The case of the Walnut Grove Dam, I think, brings out your suggestion very forcibly. There was a water-shed of about 325 square miles. Under any ordinary circumstances, under any ordinary rain-fall, there would have been no danger of overflowing that reservoir; but, on the other hand, those who have been acquainted with Arizona for a considerable number of years are aware that every now and then there comes an exceptional storm, and engineers who have made a special study of the subject of reservoirs and the storing of reservoirs are well aware that when the precipitation comes very rapidly and very suddenly there is a tendency to a definite ratio between the amount of rain-fall and the amount of run-off, so that there is a possibility of making a computation of the amount of water that is likely to flow into a reservoir when the rain-fall exceeds a given amount in a given number of hours; and, now, it seems to me that the engineer who had charge of that work should have studied that problem more than he did; that he could have foreseen that there was a liability of such a rain-fall, and the precedents which have been given by the English engineers in India and by the Italian engineers in the Piedmont should have been ample to warn him of the possibility of such an accident as that.

Senator REAGAN. Was there not some defect about the masonry?

Captain DUTTON. I think not.

Senator MOODY. How large was that dam? What was the length, width, and height of it?

Captain DUTTON. The dam was 110 feet high. The bottom of it I am not accurately informed about. I have made some inquiries on the subject, but have as yet received no reply. I understand, however, that the basal dimensions were ample. It belongs to a type of dam which has become very popular in California of late, which is known as the loose-rock dam. There are some great advantages about a loose-rock dam. A leak is of very little consequence.

Senator MOODY. For what reason?

Captain DUTTON. Because the water which flows through the front of the dam flows through the back, through the interstices of the stones, and exercises no internal pressure. If water gets into a dam constructed of masonry—gets inside—it is likely to burst it by hydrostatic pressure and destroy it; but in a loose rock dam there is no danger of that kind.

Senator MOODY. No danger of undermining?

Captain DUTTON. No danger of the undermining or bursting of the dam.

Senator MOODY. At what point from the bottom did this break occur?

Captain DUTTON. It occurred at the top, by the overflow of the dam. The waste-weir being insufficient to carry off the water, it began to overflow. If you have a dam of such great height as that and the water is permitted to overflow it, its destruction is absolutely certain.

Senator MOODY. A fall of water 110 feet makes a pressure of how much to the square inch?

Captain DUTTON. Well, it depends whether it falls unchecked or is checked.

Senator MOODY. Unchecked, as it would flow over a dam.

Captain DUTTON. The pressure would be terrible It would be a difficult matter to compute. Its destructive power would be great.

Senator MOODY. I desire to ask a question on another branch of the subject. You say there was $110,000 of this $250,000 that was assigned to the engineering and hydrographic surveys?

Captain DUTTON. Yes, sir.

Senator MOODY. And $120,000 was assigned to the topographic survey?

Captain DUTTON. Yes, sir.

Senator MOODY. Can you state generally for what the balance of the $110,000 was expended?

Captain DUTTON. There was allotted to Montana, $9,500; to Colorado, $19,500; to New Mexico, $8,500; to Idaho, $10,000; to Nevada, $15,500; to California, $13,000; making $76,000 for engineering work.

Thirty-four thousand dollars was allotted for the hydrographic work, making $110,000.

Senator **MOODY**. Commencing with Montana, please state where and in what work that was expended?

Captain **DUTTON**. A large proportion of it was expended in making surveys of the Sun River Valley and in making reconnaissances of the Yellowstone and the Three Forks of the Upper Missouri and the country lying between the Yellowstone and the Missouri Rivers.

Senator **MOODY**. What practical work was done in the Sun River Valley? Were any reservoir sites selected or lines of canals or ditches run?

Captain **DUTTON**. There were ten reservoir sites first selected, of which one was rejected, as being impracticable. The remaining nine were carefully surveyed, and the dam sites were thoroughly contoured on a very large scale, and the survey brought to such a condition that estimates of the cost of construction can be made at any time, whenever a Board of Engineers can agree upon what is the most suitable form of dam to be constructed. There is a high-line canal, taking water from six to nine reservoirs, which constitute a system, and bringing the water out upon the bench lands above Sun River, where it can be utilized.

Senator **MOODY**. Do you take the water from all those reservoirs into one canal—one general canal—or do you run a canal from each one of these reservoirs?

Captain **DUTTON**. A high-line canal takes the water from all the reservoirs; so they are practically one system.

Senator **MOODY**. Is that the mode of expenditure of the balance of the money, generally speaking, in all the States and Territories you have mentioned?

Captain **DUTTON**. That is not the exclusive method of the engineering work. In the Arkansas Valley the work has been somewhat different. It has there been devoted partially to the same end, that is, to devising a unified scheme for the maximum development of the irrigation possibilities of that hydrographic basin.

Senator **MOODY**. That is, selecting sites?

Captain **DUTTON**. Selecting sites and estimating the cost of construction.

Senator **MOODY**. Carefully surveying the sites?

Captain **DUTTON**. Yes, sir.

Senator **MOODY**. Locating the sites of dams?

Captain **DUTTON**. Yes, sir.

Senator **MOODY**. What else?

Captain **DUTTON**. Preparing surveys which can be utilized at any time.

Senator **MOODY**. Which can be utilized for the distribution of the waters.

Captain **DUTTON**. Yes, sir.

Senator **MOODY**. Outside of that what special work has been done?

Captain **DUTTON**. In addition to that there has been the selection of a large number of possible reservoir sites, which up to the present time have not been co-ordinated with any particular system, but which may be co-ordinated at any future time. Furthermore, there has been a considerable amount of money expended in the segregation of irrigable lands.

Senator **MOODY**. What do you mean by the segregation of irrigable lands? Do you mean the ascertainment of the areas of the lands that are susceptible of irrigation?

Captain DUTTON. The law provides, as you will remember, that all of the lands which are rendered susceptible of irrigation by such hydraulic works as are mentioned in the law are withdrawn from occupation, sale, and entry. Of course it is necessary to specify what those lands are, giving the township, range, section, quarter section, etc. Now there are a great many lands about which we are uncertain, but there are still others, of very large extent, about which no uncertainty exists, and it was deemed best to take those instances where no uncertainty existed at all and have them reported to the Secretary of the Interior for withdrawal from entry, occupation, and settlement, and do it promptly.

Senator MOODY. You have ascertained, then, by your surveys, the areas of lands susceptible of irrigation and that can be brought under irrigation by means of this system of reservoirs and distributing works that you have been planning?

Captain DUTTON. Yes, sir.

Senator MOODY. And marking upon the ground?

Captain DUTTON. We took the Land Office surveys. They are marked on the ground, in most cases. We took the Land Office plats, and from draughts of the Land Office plats we made our own draughts and certified them to the Department.

Senator MOODY. Do you do that by survey or mere observation?

Captain DUTTON. By sending a competent party upon the ground to identify the corners.

Senator MOODY. Will you state generally, as briefly as you can, how the $120,000 which was assigned to the topographic service has been expended?

Captain DUTTON. I only know in a general way where the field-work has been?

Senator MOODY. I am only asking for the information you have gathered from your familiarity with the office work.

Captain DUTTON. I can only state that from my general knowledge of where the work has been carried on. There have been a number of field parties at work in the Sierra Navadas, along the boundary line between California and Nevada. There has been a field party at work in the Snake River Valley, in the vicinity of Idaho. There has been a very large field party, or series of parties, at work in the Arkansas Valley in Colorado. There has been another large party at work in the valley of the Yellowstone and on the upper forks of the Missouri,—and a year ago—I am not certain whether it is within the present year or not, but a year ago there was a party at work in the Rio Grande Valley, in New Mexico. I am not certain whether they have been continued during the present fiscal year or not.

Senator MOODY. What work do these parties do that is of value so far as the purposes of irrigation are concerned, except to furnish these information maps that you have spoken of, that you take and then go upon the ground to locate absolutely the reservoirs by actual surveys? What service have they performed in the direction of irrigation?

Captain DUTTON. Well, there are two stand-points from which that question can be answered.

Senator MOODY. I would like your views upon it.

Captain DUTTON. I think I had better answer it——

Senator MOODY (interposing). What I am trying to get at is this: I would like to know, if the committee has the patience to allow me——

The CHAIRMAN (interposing). Certainly.

Senator MOODY. I would like to know how much of this $250,000 has been expended for the purpose of irrigation and how much has been expended for the purpose of mapping and platting the country. In that light I would ask you, captain, what work the topographic parties have done.

Captain Dutton. I think the best answer I could give you would be to try to explain the matter from the stand-point of the Director himself.

The Chairman. Give the engineers' views and the Director's, both.

Senator Jones. It seems to me that you are likely to bring about confusion here. A topographic map may have great value in many different ways. It may or may not be necessary to have it for the purposes of irrigation. I do not believe you can have an intelligent method of irrigation without a topographic survey; but when a topographic survey is made it can be——

The Chairman (interposing). We want his view.

Senator Moody. I understood the captain to say—and I may have misunderstood him—that the topographic surveys which were important for irrigation purposes were made by the engineering surveys.

Senator Jones. He said those that were indispensable.

Senator Moody. They must have these vertical surveys.

Captain Dutton. And on a very large scale.

Senator Moody. On a very large scale; in other words that the mere togographer does not undertake to fix with any degree of accuracy the line of any canal or the altitude of any place, except for mere topographic purposes, and that after he is through with his work, or if he does not do the work, the engineering corps that is engaged in locating dams and reservoirs, and canals for the distribution must go upon the ground and make exact and accurate surveys. Of course every man understands that if you are going to run water from a reservoir you have to run some sort of levels, and run them with accuracy, and that a mere topographic survey will not do; but the topography you speak of, as I understand it, is that topography which comes from these accurate survey by engineers. Am I correct?

Captain Dutton. That is correct; entirely so. To answer your question as you originally put it, I would say this: It was the Director's idea originally to have a topographic map constructed with a degree of accuracy which would be sufficient to enable engineers to dispense with costly and cumbersome parties of transitmen and levelers, and to produce maps which, taken in the hands of the engineer and carried into the field, would enable him to lay down his canal lines with as fair a degree of accuracy and certainty as if they were actually run by transit and level. That was his way of making an irrigation survey. I think that the Director was under a misapprehension as to the degree of accuracy in his maps which was attainable by the methods actually used by the topographers and under the requirements which were laid upon them. My belief is that no such degree of accuracy as would be necessary for the engineer was at all attainable by the methods adopted by the topographers, and I am quite confident that the topographers think the same way themselves, with the possible exception of Professor Thompson. That was the Director's desire in having a topographic map made.

The Chairman. Now, give the engineers' side of the question.

Captain Dutton. The engineers' side of the question, I suppose, would be this: That a topographic map can not by any possibility be made with any such degree of accuracy as is required for the crudest and most general purposes of the engineer. In the next place, the requirements of the engineer are for a very large scale map, a map merely of a strip of ground a few hundred feet wide along the path of his traverse; also for a very detailed map, on a scale never less than 200 feet to the inch, and most generally 100 feet to the inch, sometimes 50 feet to the inch for dam-site purposes. This minute survey on a very large scale is to enable the engineer to take the map into his office and estimate quantities, as we say. Similarly, also, the survey along the line of his traverse on a very large scale is necessary for precisely the same purpose as the railroad engineer makes it, in order to be able to estimate the quantity of excavations he has got to make and how to adjust his cuts and fills.

Senator MOODY. Pardon me for referring to another subject. What is the lowest grade of flow which you provide for in the canals or ditches to which you have referred?

Captain DUTTON. The lowest grade that I know of for a canal is about eight-tenths of a foot to the mile. The tendency among engineers is to adopt lower grades than they used to in high line canals, and if the country and economy of work will admit of it, they now prefer rather lower grades than they have ever used before.

Senator MOODY. How much is that to the rod?

Captain DUTTON. I should have to apply the arithmetic to it. It would be a very minute fraction of an inch.

Senator MOODY. Now, with that fall of grade what is the percentage of evaporation as the water passes through the canal; or let me ask, primarily, what is the degree of evaporation?

Captain DUTTON. There is no way of stating evaporation, Senator, except——

Senator JONES (interposing). In proportion to the surface.

Captain DUTTON. There is no way of stating evaporation except by ascertaining the amount of water evaporated in a given time, so many hundredths of an inch in a day, or so many inches in a month, or so many feet in a year. That is the only way in which we can state evaporation.

Senator MOODY. I have heard it asserted by hydraulic engineers that the average evaporation in a canal or ditch running slowly, as you have indicated would be the case, of course with a fall of eight-tenths of a foot to the mile, was about 3 per cent. a mile.

Senator JONES. Three per cent. of the volume of the water?

Senator MOODY. Yes, of the water in the canal or ditch.

Captain DUTTON. When I say that eight-tenths of a foot to the mile is the smallest grade that I know of I do not wish you to understand that is the grade for any great length of a canal. It is for only a certain portion or section of the canal, where certain reasons necessitate the use of a minimum grade. A minimum grade should not be resorted to in all cases. What the engineer wants is a grade which will enable him to get his water from the source of supply to where it is required in the shortest possible time. If he gets his grade too great, it will wash out his canal; if he gets it too low, it will increase the cost of construction.

Senator MOODY. The extent of evaporation depends largely upon the surface which is covered by a given amount of water?

Captain DUTTON. It is always in proportion to the surface, other things being equal. We consider that evaporation depends on three quantities: The first is the temperature of the water; the second is the absolute humidity of the air. There is still a third, the rate at which the wind is blowing, the wind factor being really the most important and the most difficult to handle.

The CHAIRMAN. I desire to ask one or two questions, and I want to call the attention of the committee to this matter. In constructing dams in northern Arizona, Nevada, New Mexico, parts of Utah, and parts of Idaho, where they have cloud-bursts in summer and violent storms sometimes in winter, that produce unusual floods, would any general topographic survey be of as much use to you as a particular examination of a given stream, with a view of ascertaining the evidences of what had happened there in the way of floods in the past? For example, if you have been through that country you have seen places where these cloud-bursts to which I have referred have occurred, carrying down immense rocks weighing hundreds of tons and gullying out deep ravines in the bald mountains, where the precipitation generally starts. Are there not evidences on the ground which would warn a person familiar with the country to build no dam under any circumstances in certain places, no matter what the topography might indicate? Are there not such places?

Captain DUTTON. Plenty of them.

The CHAIRMAN. Where any dam would be torn out. I have in mind a cañon in California—Panamint Cañon—which is very narrow and very steep. At the foot of that cañon there are immense rocks, some of them 50 or 60 feet high, which have been carried down through the cañons by the floods, by these cloud-bursts which prevail there, which occur frequently. To build a dam there would be folly. Now, when you deal with that country is it not more necessary than anything else to observe the evidences on the ground, ascertain the experience of those who have lived in the region, and if you are going to utilize that water take the water out of the stream and build your reservoir somewhere else? In dealing with a country like Arizona, is it not one of the first things to do to see what nature has already done and avoid those places where these cloud-bursts have occurred, and would a topographic map be of very much use to an engineer who is sent on the ground to find a safe place to locate his dam?

Captain DUTTON. It would not be of any special use.

The CHAIRMAN. It would be convenient to show the geography?

Captain DUTTON. Yes, sir; but when it comes to practical work, it would not be of any particular use.

The CHAIRMAN. What delay would be necessary in this work if we should wait for sufficiently accurate topographic surveys to precede the engineering work?

Captain DUTTON. A good many years, unless the topographic survey was conducted so as to meet the wants of the engineers at the very start.

The CHAIRMAN. Is there any topographic survey now in existence that is sufficiently accurate for use in locating a dam and line ditch without this same engineering work which you speak of?

Captain DUTTON. I think that probably some of the English ordnance survey maps might——

The CHAIRMAN (interposing). I mean in this country that has been made by any of the surveys you have mentioned?

Captain DUTTON. I do not think there is.

The CHAIRMAN. You are familiar with what has been done. Take for example this district. Do you know of efforts having been made to secure an accurate topographic map of this?

Captain DUTTON. I know the Coast Survey made some good maps during the war, and I think the city engineer has run some careful surveys.

The **CHAIRMAN**. Has not the Coast Survey been at work for the last few years in trying to make an accurate map?

Captain **DUTTON**. Possibly they have.

The **CHAIRMAN**. You have not seen that map?

Captain **DUTTON**. No, sir.

The **CHAIRMAN**. Do you know whether that map of the District of Columbia, on which they have spent so much money, is sufficiently accurate for locating a line of railroad, or a ditch, or a dam? Could you do those things by that map without engineering work? I suppose that is the best map we have in the United States.

Captain **DUTTON**. I would have to study the map before I could form an opinion.

The **CHAIRMAN**. You have not studied the map?

Captain **DUTTON**. No, sir.

The **CHAIRMAN**. Then we need not, in your judgment, wait for the topographic survey to prosecute what surveys are necessary for immediate use.

Captain **DUTTON**. I do not think it is necessary.

Senator **REAGAN**. Captain, has the hydrographic and engineering work covered the whole ground of the topographic work? If it has not, what proportion of the topographic work has been covered by the hydrographic and engineering work?

Captain **DUTTON**. While the topographic and engineering work are in most cases in the same neighborhoods, the only case of actual coincidence is in the Arkansas Valley. The topographic work was commenced there about a year and a half ago, I think, and the engineering work only last summer. In all other portions of the West the two fields of labor have not coincided.

Senator **REAGAN**. If you should take a topographic map, according to the way the work is now being done, could you not lay down a common road or railroad by it?

Captain **DUTTON**. You could point out in a general way, perhaps, where a common road might be laid out. I think, however, there are some portions of a topographic map where that would be very doubtful. As to a railroad, I should say no. It would not dispense with the necessity of a railroad survey.

Senator **REAGAN**. You could get the general line of a railroad from it?

Captain **DUTTON**. Well, in a general way you could. I think so.

Senator **REAGAN**. Can you take a topographic map and select any particular stream and determine the catch basin of that stream by it and the amount of land that would be irrigable?

Captain **DUTTON**. No, sir; you would have to go over the ground to ascertain the amount of irrigable land.

Senator **REAGAN**. Where it is above 4 feet altitude you could get the place where your reservoir would have to be located, you could get the size of your catch basin, and you could determine what lands are lower than your dam?

Captain **DUTTON**. They only make the maps with 20-foot contour.

Senator **REAGAN**. Then I have been wrongly informed at the Department, for I was told there that they had made the maps on a 4-foot contour.

Captain **DUTTON**. Possibly it may be that in the Mississippi Valley.

Senator **REAGAN**. No, I am talking about the Western country.

Captain **DUTTON**. It is a 20-foot contour, unless they have changed without my knowledge very recently. I know a few months ago it was understood to be 20-foot contours in the valleys, 50-foot in the foot-hills, and 100-foot in the mountains.

Senator **Jones**. You say a topographic map is of very little value to the engineer in locating irrigating works.

Captain **Dutton**. I think they are of only general value.

Senator **Jones**. And are by no means necessary.

Captain **Dutton**. I do not think they are necessary within the meaning of the law, and yet there is this to be said about it: The term "necessity" has a practical interpretation; is not easy to define. We are every day certifying that certain things are necessary on our bills and on our vouchers. While in a certain sense and in the ordinary acceptation of the term they are necessary, in an absolute sense they are not.

Senator **Reagan**. What is the use of a topographic survey?

Captain **Dutton**. To furnish general information about the country and a knowledge of the laws of distribution.

Senator **Reagan**. Has the Government made a mistake in authorizing these topographic surveys?

Captain **Dutton**. No, sir; I think not. I think no money has been better spent.

Adjourned.

Department of the Interior, U. S. Geological Survey,
Washington, D. C., March 31, 1890.

Dear Sir: I have the honor to acknowledge the receipt of your letter of 29th instant, desiring me to inform you concerning the expenditures made in the Geological Survey under the appropriations made in 1888 and 1889 for irrigation surveys, viz:

First. Of the exact amount of the two appropriations of 1888 and 1889, the first for $100,000 and the second for $250,000, which was assigned to topographical work and to engineering surveys for irrigation purposes, and how much has been used in the office for topographical work and how much for the work of irrigation.

Of the first appropriation for $100,000, the sum of $40,000 was at first allotted for engineering and hydrographic work, but at a later period $4,000 of this sum was transferred to the allotment for topographic work, making the allotment for engineering and hydrographic work $36,000 for the fiscal year ending June 30, 1889. A sum of $4,000 was understood to be reserved by the director for office expenditures. The amount finally allotted for topographic work I understand to have been $60,000. As regards the last two items, however, my statement is not necessarily conclusive, since I have had no formal or official notification thereof. As to how much has been used in the office for topographical work and how much for irrigation work, I can not give a complete answer except by stating the general nature of the case.

There are numerous expenditures, such as heating, lighting, watchmen, messengers and clerks in the Director's office, purchase of stationery, printing, express charges, carpenter work, repairs, etc., which are for the common benefit of all branches of work under the Director's administration, and it would be impracticable to charge these expenses to the several allotments except in an arbitrary way. They become, therefore a charge against the reserve funds which are divided off from each appropriation. Moreover, it is usually the case that expenses slightly overrun the the allotments, and the excess is paid from the reserve fund at the end of the fiscal year. The work under my charge overran the $36,000 allotted by the amount of $743.33. How much the topographic work overran its allotment I do not know.

During the present fiscal year the sum of $110,000 ha sbeen allotted for the engineering and hydrographic work. My understanding is (though I have not been informed officially to that effect) that $120,000 has been allotted to topography and $20,000 held as a reserve fund. To what extent the allotments will have to draw on the reserve fund at the close of the year can not, of course, be exactly foreseen at present. Up to this date there are charges for work under my control amounting to $3,667.44 which were not estimated for at the beginning of the fiscal year and which will become a proper claim against the reserve fund. I do not now see any reason to expect that this amount will be materially increased. Of the state of the topographic allotment I have no information.

If I rightly apprehend the purport of your first inquiry, your desire is to know what disposition has been made or is intended to be made of the three portions (engineering, topography and reserve) into which the appropriation has been divided by the discretionary action of the director. With that understanding, the nearest approach which I can make to the exact information you seek is as follows:

From the first appropriation of $100,000, $36,743.33 have been explicitly expended for the engineering and hydrographic work. For the topographic work, I understand that $60,000 have been allotted and presumably expended. Of the remaining $3,492.23 I have no knowledge beyond the fact that there have been numerous sources of necessary incidental expenditure to which it may have been applied for the common benefit of both the engineering and topographic work without being distinctly chargeable to either one alone. A portion of it might also have been available at the end of the fiscal year to meet expenses in excess of the allotment for topography.

Second. You further inquire how much of the entire expenditure was for topographic work during the last fiscal year in the region west of the one hundredth meridian and whether the topographical work of the arid region since the appropriations for irrigation has been carried on with money for topography or with money appropriated for irrigation.

I have not the full information and knowledge which are necessary to give an exact answer to this question or to furnish the figures. But in general terms, I understand that on July 1, 1888, topographic parties were at work in the arid region under the appropriation for topography only, and continued to work so during the remainder of the summer. The first appropriation for irrigation became a law on October 2, 1888, and within a very few weeks parties were put to topographic work in the Arkansas basin at the expense of the irrigation appropriation, and in the spring other parties took the field in California, New Mexico, and Montana under the same appropriation. During the current fiscal year my understanding is that all of the topographic work of the arid region has been at the expense of the irrigation appropriation and that no portion of the topographic appropriation has been expended there.

Third. In what section was the first $100,000 appropriated for irrigation expended in engineering work for irrigation and what amount of irrigation survey was completed with the first appropriation and what area of land was covered? Where has such portion of the second apprppriation as was assigned to irrigation been expended, and what was accomplished in each district?

Immediately after the passage of the appropriation October 2, 1888, measures were taken for organizing the hydrographic work. As the funds could not become available until the 1st of November, when the winter would be upon us, it was deemed unwise to immediately organize the engineering work. For the hydrographic work skilled men of high intelligence were necessary, and there were probably not two dozen men in the United States who knew how to gauge a stream, and not one of the few who did know were available. It is an art requiring manual skill, the intelligence of an educated hydraulic engineer, and the temperament of a somewhat scientific observer and manipulator. Neither was there any well-established and generally-accepted method of stream gauging, nor any standard instruments. In short, there was no regular practice. It was necessary, therefore, to create men, methods, and instruments. It was believed that good gauging would be impracticable in wintertime, and of little value even if it were practicable, and hence that no better course could be followed than to select promising, well-educated, and ambitious young men, put them into a camp of instruction in a moderately warm climate during the four or five months of winter, and let them acquire the necessary skill, work out methods of gauging, and ascertain by trial the best kinds of instruments to be used. This was done. A good comfortable camp was established on the Rio Grande in New Mexico, and fourteen young men sent there early in December. They applied themselves with great zeal and interest, and with two or three exceptions proved to be most excellent men. When the spring approached I had about a dozen men at my command who knew what was wanted of them and how to do it. Up to the 1st of April the expense of the work for all purposes was $10,400. The men were then distributed to their stations; two in New Mexico, two in the Arkansas Valley, one in California, one in Nevada, two in Utah, one each in Arizona, Idaho, and Montana, and one at El Paso, Tex. Gauging stations were established in the following basins:

Rio Grande and tributaries, 6 stations; Gila and Salt Rivers, 3; Carson and Truckee 7; rivers of Utah, 14; Snake River basin, 5; Upper Missouri and Yellowstone, 12; Arkansas basin, 6.

Evaporation stations were also established at El Paso, Phœnix, Yuma, Clear Lake, California; at several localities in Utah, two in Idaho, five in Montana, and two in Colorado. About seventy special stations were established at high altitudes in Arizona, New Mexico, and Colorado for observing rain and snow fall at places not reached by the Signal Service. Many hundreds of gaugings were performed and a large amount of special inquiry made into the duty of water. At the close of the fiscal year the work was progressing in a highly satisfactory manner except in the Carson and Truckee basins, and though the work here was not what was expected it has proved to be less faulty than was at one time feared. Everywhere else it has been better than was anticipated for the first season.

The engineering work was not organized until spring, first, because winter work is undesirable unless an emergency demands it, and, second, because the allotment at my disposal was insufficient to accomplish any work of much value. In May two supervising engineers, Messrs. Hall and Nettleton, were appointed, and four division engineers, Messrs. Foote, Bodfish, Bridges, and Wilson. The funds remaining available would not admit of more than buying the outfits and putting the parties in the field in time to accomplish three or four weeks' work, *i. e.*, just make a beginning of their work, by the time the fiscal year closed. The parties were launched in the Arkansas basin under Mr. Bodfish about June 1; in the Snake River basin under Mr. Foote about the middle of May; in Montana under Mr. Wilson about June 1; and in the Truckee basin under Mr. Bridges about the middle of June. At the close of the fiscal year it may be said that something had been begun by the engineers but nothing had been completed.

The only segregation work was the withdrawal of Utah Lake and Bear Lake as reservoir sites, which were carefully surveyed for that purpose by two of the hydrographers.

The total cost of the engineering work, including all expenses, direct and indirect, up to June 30, 1889, was $7,550.19, of which the greater portion was for the outfitting of the parties The total cost of the hydrographic work and the expenses of my own office, including also the purchase of a large number of new instruments of a costly kind, was $29,193.14.

Under the second appropriation the following work has been done:

There have been practically seven divisions of engineering surveys, one of which was not anticipated at the beginning of the year, viz, Utah, but was opened in consequence of special orders of the Secretary of the Interior.

First. Montana. Mr. Wilson began his work by an energetic reconnoissance of the valleys of the Yellowstone, the Gallatin, the Madison, and the Jefferson, the Missouri between Bozeman and Great Falls, the Sun River, and the upper portion of the Musselshell. He went alone on horseback, with only a hand-level in his pocket, and in the course of a little more than three months reported sixty-three large reservoir sites for withdrawal, and about 11,000,000 acres of land for segregation. The reservoir withdrawals were well done and satisfactory in every way. Question arose in my mind concerning the segregation of so vast an area (about 17,500 square miles), but a careful examination of his report, in conjunction with a knowledge of the country, satisfied me that the doubtful questions were whether he had not omitted land which he should have included, rather than included land which he should have omitted.

Mr. Wilson soon reached the conclusion that some of the best lands in Montana might be watered by a system of reservoirs and canal, taking the flow of the Sun River. He immediately began a survey there. In the course of the season his assistant, Mr. J. B. Rogers, ran a preliminary line of a canal 80 miles long, surveyed ten large reservoirs on a scale of 500 feet to the inch, and dam sites and waste-weirs 100 feet to the inch, with 2 foot contours, all in sufficient detail to enable close estimates of cost to be made. It is a fine piece of survey work, and shows admirably how much can be done by intelligent projects and how great are the possibilities of a sound comprehensive, systematic development. The cost of the entire engineering surveys in the Montana division up to March 1, including expenses in field and office, is $6,574.71.

In the Arkansas division, Mr. Bodfish, under the immediate eye of Mr. Nettleton, was instructed to investigate the possibilities of increasing the useful water supply of that river by storage, and of utilizing its return waters upon the plains near the Kansas line. He has surveyed in great detail ten large reservoir sites in the vicinity of Leadville and Buena Vista, also one on Monument Creek, near the base of the front range. He has examined all the tributaries on the north or left bank of the river for reservoir sites, reporting twenty-five of them for withdrawal. The southern tributaries would have been examined had not the premature coming of winter buried the country deep in snow. He has, I believe, exhausted the reservoir sites so far as he has gone. He has also run a canal line, starting from near Granada, above Garden City, a distance of 146 miles, to test the question of using the return waters in the river upon lands of western Kansas. The project of utilizing Twin Lakes for a reservoir is a most promising one and the survey work has been done in a highly satisfactory manner. The total expenditure in this division up to March 1 is $9,466.13.

In the Rio Grande division the engineering work was not started until July. Mr. W. W. Follett was appointed division engineer. He at once began the survey of a project for a dam and reservoir at El Paso, and completed his survey about the last of August. It included a contour and cross-section survey of the great reservoir basin, with close estimates of capacity; sounding the quicksands in the bed of the river to ascertain the surface of the bed rock in two sections of the river; a close survey of the two dam sites, and a relocation survey of the Southern Pacific and Atchison, Topeka and Santa Fé railroads. His report of a project, with estimates of quantities and of cost, has been submitted.

During the winter Mr. Follett has been engaged in the segregation of irrigable lands in the Rio Grande Valley in New Mexico. He was instructed to proceed to the office of the Surveyor-General in Santa Fé and prepare a compilation of the Land Office plats of that valley, and to then make a close detailed segregation, denoting all land grants, railroad grants and all claimed lands, section by section, and to verify the segregations upon the ground. Also, to select all possible reservoir sites and report them for withdrawal, and all natural dam sites, whether on the main river or its tributaries. He was to begin his work at Fort Seldon and work northward to the Colorado boundary, cleaning up as he went. He has sent weekly reports of his itineracy and lists of specifications of selected lands, and is now within about 60 miles of the Colorado line. He has reported about sixty reservoir sites. The amount of land reported I have not computed, but it will be some millions of acres. This careful segregation was deemed necessary here by reason of the tangle of land grants and other claims in various stages of adjudication. The cost of the El Paso Reservoir surveys was $2,210.59. The cost of the segregation work up to March 1 was $1,744.10.

In California a survey was made of Clear Lake to ascertain its possibilities as a storage reservoir. This was an extensive survey and the work was of a high order and in the most thorough detail; in fact, I think it will rarely happen that so extensive a survey will be called for.

A well-equipped party was also sent into the mountains around the headwaters of the Stanislaus, Tuolumne, and Merced Rivers to search for reservoir sites. Eight good sites were found and were surveyed. Some doubtful ones were also discovered and marked down for further examination.

A reconnoitering party of two men was sent into Lassen and Modoc Counties, east of the Sierras, to search for reservoir sites, and found two very large ones with a considerable water supply. This party expended a large amount of money and accomplished but little.

A fourth party was sent to Owen's Valley to segregate irrigable lands and examine the headwaters of the river for resernoir sites. They were instructed to make a close segregation in the same manner as Mr. Follett was in New Mexico. They completed the segregation work in the lower valley for a distance of about 100 miles along the river front and were about to proceed to the upper valley when the early severe storms set in and put an end to the work. Their results have been reported in a satisfactory manner as far as they went. The total cost of the work in California was $11,483.47 to March 1.

In the Truckee and Carson basins Mr. Bridges made detailed surveys of Donner, Independence, and Webber Lakes as reservoir sites. A survey was made for a reservoir in Long Valley, with canals taking water across the Carson River to the lands on the east side of the Carson Valley. This last survey was not approved, nor was it authorized or intended. A survey was also made of Hope Valley at the headwaters of the west fork of the Carson. A trial line was surveyed from a point about 5 miles above Wadsworth to the lands southeast of that town to ascertain the possibilities of carrying water to them from the Truckee River. A large amount of canal line was surveyed by Mr. Bridges, but as none of the others was authorized or approved no further mention is made of them. His management of his division being very unsatisfactory he was relieved from duty by me, and at my request was asked by the director to resign. The surveys of Donner, Independence, and Webber Lakes and of Hope Valley are of some value, but not commensurate with the expenditure. The accounts of the engineering work in this division were closed on the 30th of September, and at that time the expenditures were $13,495.36. Since that time further office expenses were incurred in the office of the supervising engineer, Mr. Hall, which bring the total amount to about $15,500. The exact figures it would require considerable labor to extract from the itemized vouchers. They appear on my books with the expenses of the office of the supervising engineer.

In Utah it was originally intended to do nothing but hydrographic work, but circumstances forced other work upon us. Mr. Newell, as hydrographer, was found to be an object of great interest to the people of the Territory, who sought his official action with great eagerness. He was soon required by me to make a survey of Utah Lake, which was done in the preceding year. It soon became manifest that numerous other reservoir sites ought to be examined, and this was done and the sites were withdrawn but not surveyed. Later, an order was received from the Secretary of the Interior to segregate the irrigable lands in Bear River Valley. Instructions were therefore given Mr. Newell to make a close segregation, section by section, and to verify his work on the ground, and also to add to it some traverse and level work to clear up doubtful questions in some localities where disputes or complications by reason of existing claims and filings might arise. The work was speedily accomplished. Over 2,000,000 acres were reported for segregation, and a plat of the work, based on the Land Office plats, was furnished and duly certified. The cost of the segregation work was $1,579.56.

In Idaho Mr. Foote was instructed to survey thoroughly a project for a pair of grand canals, taking water from the Snake River at Eagle Rock, one branch running south to Pocatello, the other running west into the desert. This was to be only a single feature of a comprehensive system of canals and reservoirs for utilizing as much of the water of the river as could be stored in addition to its natural flow. An excellent dam site with an ample waste weir was found at Eagle Rock, and a location survey was begun at once without any preliminaries on the left bank, and carried 70 miles to Pocatello, where the line was tailed into the Portneuf.

The line was carried on to the westward nearly to American Falls, where it was found to be impracticable to carry it further. A new line was started at American Falls, and carried only 14 miles, as it was found to be impracticable. Another line was surveyed from the Snake near Minedoka, but was not completed, owing to stormy weather. It was found to be practicable.

Mr. Foote also made a reconnaissance up the forks of the Snake River in search of storage capacity. An indefinite amount of it was found at Jackson Lake, but present appearances indicate that the whole annual flow of the fork issuing from Jackson's Lake would probably be not much more than 500,000 acre-feet, while the capacity of the basin is probably four or five times that amount. The dam site is excellent.

Another grand reservoir site was found in Swan Valley, much lower down, on the South Fork. Here the flow of the river is very much greater. The capacity of this site is more than a million, and may be nearly a million and a half acre-feet, with plenty of water to fill it. A good dam site with an abundant waste weir exists. Another immense site was found on the Falls River Branch of the Snake where probably 300,000 or 400,000 acre-feet could be very cheaply stored. Several other large sites were found, but not sufficiently examined to enable statements to be made with confidence concerning them.

Mr. Foote was further instructed to report all irrigable land in the valley of the Snake above American Falls for segregation, and he has reported over 10,000,000 acres.

During the past month he has begun a location survey of the other canal, taking water at Eagle Rock on the other side of the Snake, and his parties at last accounts were in the field. Before the close of the present fiscal year it is expected that more than 100 miles additional of canal line will be surveyed. These location surveys of Mr. Foote are done in a very thorough manner, and his drawings are cross-sectioned and afford the means of making estimates of cost. His plats have been received and are apparently excellent work. The total cost of the engineering work of this division up to March 1, has been $9,590.19.

It remains to add the expenses of my own office and those of the supervising engineers, of which separate accounts are kept. The salaries of the supervising engineers are included in them, my own salary being paid from the appropriation for the Army: Chief Engineer's office $7,119.39; Mr. Nettleton's office, $4,966.87; Mr. Hall's office, $7,151.50.

My own office includes a disbursing agent, who does all the disbursing under my charge; a single type-writer; two draughtsmen, who prepare all the segregation work for the General Land Office, have charge of the engineering maps and drawings, their proper recording and filing, also of the hydrographic records and reductions and miscellaneous draughting work.

As regards the hydrographic work during the fiscal year I may speak more briefly. Many of the chief rivers of the west have been put under thorough observation by gauging and by continuous records of rise and fall. They are the Arkansas, the Rio Grande, the Gila and Salt, the Carson and Truckee, all the rivers which flow into Salt Lake and Utah Lake, the Sevier River in Utah, the Snake with its forks, the Wood River and Lost River in southern Idaho, the Weiser, Payette and Owyhee, the Missouri, the Yellowstone, the Gallatin, Madison and Jefferson, and the Sun River. Many of these have observing stations at several points and on their minor tributaries not specified. We now have continuous records worked out, computed and exhibited in diagrams, showing their daily discharges for the whole summer and until the rivers were closed by ice. In the southern territories the records are continuous throughout the winter. The hydrographic work has, on the whole, gone on with better success than was expected at the start, and much credit is due to the young men who have accomplished it. The work, however, gives plain indications of being somewhat starved by reason of excessive but unavoidable economy. But another year will, if permitted to continue, show a very great advance. The total cost of the hydrographic work from July 1, 1889, to March 1, 1890, has been $19,984.72.

The following is a summary of the work done and the cost:

Reservoirs fully surveyed to estimates.

Montana	10
Colorado	10
El Paso	1
California division	9
Truckee and Carson	5
Total	35
Reservoirs reported for withdrawal	144

Canal lines fully surveyed to estimates.

	Miles.
Snake River Basin	157
Arkansas River Basin	146
Total	303

Canal lines roughly surveyed.

	Miles.
Montana, Sun River	80
Truckee Basin	22
Total	102

NOTE.—About 160 miles of canal line were surveyed in the Truckee and Carson Basins, but only 22 miles are accepted by this office.

Number of acres of land reported for segregation, about 30,000,000.

Cost of work.

	First appropriation.	Second appropriation.	Total.
Hydrographic	$29,193.14	$19,984.72	$49,177.86
Engineering work:			
Montana division	1,080.11	5,494.60	6,574.71
Arkansas division	1,308.94	8,157.19	9,466.13
Rio Grande division		3,954.69	3,954.69
California division	605.01	10,878.46	11,483.47
Truckee and Carson	2,314.01	11,181.35	13,495.36
Utah		1,579.56	1,579.56
Snake River	2,242.12	7,348.07	9,590.19
Supervising engineers		12,118.37	12,118.37
Total engineering	7,550.19	60,712.29	68,262.48
Chief Engineer's office		7,119.39	7,119.39
Aggregate	36,743.33	87,816.40	124,559.73

Very respectfully, sir,

C. E. DUTTON.

Hon. WILLIAM M. STEWART,
United States Senate.

SIXTH DAY'S SESSION.

WASHINGTON, D. C., *March* 14, 1890.

The committee met pursuant to adjournment.

Present, the chairman, and Senators Reagan, Jones, Moody, and Casey.

FURTHER STATEMENT OF DIRECTOR POWELL.

The CHAIRMAN. Major Powell, the point that the committee desires your views upon this morning is as to the necessity of topographic surveys preceding the engineering surveys for irrigation, the relation of the two classes of surveys, and whether the engineering surveys can be carried on independently of the other, or whether they are necessarily connected.

Director POWELL. Mr. Chairman, there are two branches of the subject which I wish to present: First, the plans and methods of the survey, as necessary to carry out the provisions of the statute; and second, I wish to call attention to and review the statutes and the reports which I have made to Congress on calls from the Senate which represent the needs of an irrigation survey, for the purpose of showing that the wording of the statute and the representations made by me to the Congress prior to the passage of the statute are in harmony with what has actually been done. That is, I wish to show, first, what the irrigation survey should be, what is necessary to be done, and the information required; and second, to show that before the passage of the law I had fully set forth the facts to Congress, and that the wording of the statute calls for the work which has actually been done.

The CHAIRMAN. We are not complaining of what has been done. We simply want to know how these surveys are dependent upon each other.

Director POWELL. These two lines I would like to be heard upon. First, then, I wish to address myself to the question, what is necessary to be done in an irrigation survey, and how can this be done in the most economic manner? The statute provides, first, that the extent to which the lands can be redeemed by irrigation shall be determined; second, that reservoir sites shall be selected; third, that canal sites and sites of other hydraulic works, such as diverting dams, etc., shall be selected; fourth, that the lands made irrigable by these hydraulic works shall be selected; and, finally, that all of these sites and lands shall be segregated—that they shall be selected on the ground, as I understand it, and be certified to the Land Office, in land-office terms of township, range, section, etc., for the purpose contemplated in the law. In order to accomplish the end a survey had to be prosecuted and a series of discoveries made. These discoveries may be divided into three classes: Those relating to the land—the catchment areas, the sites for diverting dams and canals, the sites for reservoirs, and the irrigable lands. These necessities give rise to the topographic branch of the Irrigation Survey. Second, those relating to the water; that is, it is necessary to determine the amount of water which can be used for irrigation in each hydrographic basin or area drained by one important stream and its tributaries. It is necessary to determine the mean amount of water for the irrigating season in each basin, and also the mean amount of water for the entire year, and it is also necessary to determine the minimum amount in seasons of excessive drought and the maximum amount in seasons of excessive rain-fall. It is also necessary to determine the amount of water required to irrigate an acre of land, that is, to determine the "duty" of water. The necessity for determining all of these facts in relation to water gives rise to the second branch of the Irrigation Survey, that is, the hydraulic branch. Third, those relating to estimates of the cost of dams, canals, and reservoirs. For this purpose the sites of the dams must be surveyed with accuracy and the constructive conditions as to the proximity and character of materials must be studied. The sites of the reservoirs discovered by the topographic survey must be carefully examined and plans for their construction made. The sites of canals, the general routes of which are previously discovered by the topographic survey, must be carefully run upon the ground and marked, and the amount of cutting and filling determined, and the ground minutely examined for the purpose of discovering its character, whether it be in sand, clay, gravel, or solid rock, as all of these facts affect the cost of the work. Having studied these facts the cost of construction can be properly estimated. These three classes of work all relate directly to the Irrigation Survey. They are all required by the provision of the statute, and no one can be neglected without disobedience to law. The three kinds of work give rise to three branches in its organization, which we call the topographic, hydrographic, and engineering branches.

The topographic survey is the work primarily necessary to the discovery of sites, though it has another use in the hydrograpic survey, as will be shown when that point is reached. In investigating this subject for the purpose of determining the best and most economic method of discovering the various sites required, it was decided that a topographic survey was proper. If a specific reservoir site is already known, and the body of land to be served by the waters from that reservoir is already known, the simple problem is to find a way for a canal from the reservoir to the land. Such a survey would need only the work necessary to run a number of trial lines on the ground and then to select the best from these. But the problem before the survey was not to irrigate some one man's farm from some one stream or reservoir site; it was not to irrigate some particular piece of land to suit some particular person; but the problem was to discover all of the reservoir sites, all of the canal sites, and all of the lands that could be irrigated in any given hydrograpic basin. How this could be done in the cheapest manner was the question which I had to solve. Having a specific reservoir in sight and a specific body of lands in view, and wishing to take the water from that reservoir to that piece of land, I can run trial lines and find the best route at the rate of about $25 per mile for each of the trial lines; but the final line selected must be run again with great care; the whole ground must be studied, very exact levels must be run, and all the characteristics of the line must be determined, in order that the cost of the canal may be discovered. But in the work of the irrigation survey the reservoir sites, the canal lines, and the lands to be irrigated have all to be discovered—ten, twenty, fifty reservoirs perhaps in one hydrographic basin; scores of canal lines, 10, 20, 50, 100 miles in length. To run many such trial lines over the ground for the purpose of selecting a few would involve great cost. The system of discovering canal lines by a topographic survey instead of by a trial line survey is very much less expensive. Certainly it would not cost more than one-third of the amount. To discontinue the topographic survey and inaugurate a trial-line system would be to increase the cost of the work fully three times. In the same manner the reservoir sites are to be discovered, and their relation to the streams which furnish them water and to the lands which they are to irrigate must be determined. Some of these reservoir sites are in the mountains—the best are there; some are in the valleys and on the plains. They are therefore widely scattered throughout all parts of each hydrographic basin. To discover them by trial lines instead of topographic surveys with contours would be to increase the cost of the work at least three times.

A hydrographic basin may furnish only a half a dozen good reservoir sites, or it may furnish two or three hundred, as the case may be. Some will be small, sufficient for reservoirs to hold 1,000 acre-feet of water; others will be great, sufficient for reservoirs to hold 1,000,000 acre-feet, or even 2,000,000 acre-feet of water. One reservoir site may be excessively expensive, another very economic; that is, it may cost $10 per acre-foot of water to store it, or it may cost but 10 cents per acre-foot of water to store it. It becomes necessary, therefore, for economy's sake, to select the best sites. In order to do this it is necessary to discover all of the reservoir sites of each hydrographic basin. If I were to select a score of reservoir sites in a basin at random and have these reserved to be used by the people in the future, and it should be found that half, or many, or all of them were not as good as other sites in the same basin, and that a system of reservoirs could be constructed to store the water for one-half or one fourth of the cost that would be required in the basins carelessly selected, the whole work would be repudiated by the people; it would be misleading and injurious. It is therefore necessary for me to know in each basin all of the reservoir sites in the basin, that the best may be selected. This means that I must know every valley in the basin.

To illustrate the method of discovering these reservoir sites, I have brought with me the maps constructed by the topographic survey in the upper basin of the Arkansas in Colorado. These are the maps constructed in the field. On examination you will see that they are in contour lines; that the vertical interval from one contour to another in the valley region is 25 feet, in the hill regions 50 feet, and in the mountain regions 100 feet. It is not necessary to do the work in the mountains with the same degree of refinement as in the valleys. For more than twenty years I have been engaged in making topographic surveys in connection with the other work under my charge. During that time I have employed a corps of men of ability and genius, and during that time I have topographically surveyed about a half million square miles of country, on various scales and with varied degrees of refinement. Through the inventive genius of the men who have been employed on this work new methods of survey and new instruments have been devised, so that the whole system of topographic surveying has been revolutionized, and to correspond with it the method of map construction has been greatly developed and improved. The work has been improved in quality and enormously decreased in cost; and gradually other nations of the world are adopting our system.

The topographic survey which we are making in connection with the irrigation survey is in most particulars the same that we are making for the geological survey. The topographic work necessary for the one is necessary for the other, and we were making these maps for the Geological Survey before the Irrigation Survey was inaugurated. The cost of the irrigation survey, therefore, was only the cost of what was additional to the work already in progress. The work of the irrigation survey is, for the reasons I have stated, in the first place a topographic survey, because the sites for the works and lands are to be discovered, and it is the cheapest and best way of discovering them. In the maps before you you will see that the topographers have discovered forty-three reservoir sites and marked them upon the maps. They are colored in blue. The contour lines are colored in light red, as you see, and the reservoir sites are determined by the contour lines. Each site represents a valley basin, and in general terms, the height of the dam, the size of the basin, and its capacity are revealed by the maps which the topographers have constructed. From these about twelve or fourteen have been selected by the engineers as being, all things considered, the most eligible. The twelve or fourteen must be surveyed with greater care for the purposes already indicated, that is, to determine the cost of construction and to mark them upon the ground. That is the work of the engineering branch of the survey. In the same manner these maps reveal the general lines of the canals. They show, for example [indicating on the map], that the water from this reservoir can be taken along this line to this body of land. The map reveals other lines by which it can be taken and shows that this one is the best, and the engineers have selected it and have actually run it upon the ground and obtained the facts necessary to estimate its cost.

When called upon by a resolution of the Senate for a plan for these surveys, and by the appropriations committee for an estimate of cost, I selected and recommended this method of prosecuting the work, because I believed it would be the most economic; and I estimated the cost of the topographic work, in addition to what had already been done in the country, to be about $4,000,000. In making this estimate I took into view the fact that already work had been done under the general appropriation for the Geological Survey, and that that work would not have to be done again. I further estimated that to determine the amount of water in each hydrographic basin that could be used for irrigation and the amount of land which could be irrigated thereby would cost an additional sum of $1,500,000; and finally, when it was decided by the committee that the sites should be surveyed for the purpose of estimating costs and of segregating the lands and reporting them to the Land Office as reserved under the provisions of the act, another $1,500,000 would be necessary, making in all for the irrigation of the arid lands the sum of $7,000,000. But this estimate was based upon the consideration that the work should be done in the manner which I have pointed out. If this cheap and comparatively accurate topographic method developed in the survey had not been known, and had the old methods of topographic surveying been in vogue, I should then have had to decide whether it was cheaper to make the discoveries of sites by the old method of topography or by the system of running trial lines; but having developed a more economic topographic method, it was only necessary to decide between this new method and the trial-line system; and the new method is by far the cheaper and in every way the more satisfactory; for, having done it, the entire work can be published and submitted to the people—not as the opinion of men engaged in the work, but as facts determined by instrumental survey—and presented by simple contour lines on maps, so that they can see for themselves all the facts and conditions.

Senator JONES. What is the scale of those maps?

Director POWELL. One inch to 1 mile. That is the field scale. We do not publish on that scale. It is reduced to 2 miles to 1 inch for publication.

The CHAIRMAN. Right in this connection let me make an inquiry. You have got these drainage basins mapped. Now, suppose an engineer should go into one of these drainage basins with such maps as you have, would it not be necessary, in order to do accurate work, to follow up the stream and work carefully over this ground again, to determine where to locate his reservoir and canals?

Director POWELL. No, sir. I will come to that.

The CHAIRMAN. Then could not an engineer, with the boundaries of the drainage basin indicated, go into the drainage basin and make accurate surveys and locations; or even if they were not indicated, could he not determine the boundaries of the drainage basin and do the mere engineering work with a view of practical work?

Director POWELL. No, sir; the engineer——

Senator JONES (interposing). This dotted line on the outside indicates the water-shed. [Pointing to map.]

Director POWELL. The dotted line is the catchment area. That shows what will feed this reservoir. [Indicating on map.] I will come to that in the latter part of my statement. I want to answer the chairman. An engineer who should go in there without the topographic map would have to select the site. If he went in to select the site, he would have to select it by running trial lines, and to run trial lines would cost three times this. Now, when he comes to this reservoir, the engineer surveys it, but not all this catchment area. Instead of surveying the area outlined here, he surveys this area, the dam site itself, only, and surveys it in a minute manner. The topographic survey has found the reservoir site and the catchment area. The engineer has all the facts. Now, the engineer who goes in there runs a more careful line to find the amount of water that reservoir will hold, and the length and height of dam necessary, and that is all he has to do.

Senator JONES. In order to make an accurate reservoir is it not necessary to run those minute lines?

Director POWELL. Certainly.

Senator JONES. Before the people can go in and occupy the lands these lines have to be run?

Director POWELL. Yes, sir; those in that little basin; but we have saved him all that work [indicating on map], and have done it in the cheapest possible way.

Senator JONES. This work of setting apart and getting the areas is pretty much done all over the country, is it not?

Director POWELL. No, sir; nowhere in the United States except where I have made surveys.

Senator JONES. Have you not had the engineering work in certain cases precede your topographic surveys?

Director POWELL. Yes, sir, I have, and that I wish to refer to. On the passage of the act the people of the Western region were exceedingly anxious to have results. In the general study of this subject for the twenty years in which I have been engaged, and during which Mr. Gilbert, my first assistant, has been engaged, I knew of very many sites; they did not have to be selected. I knew that Providence Lake was a site; I knew that Utah Lake was a site; I knew that Hope Valley was a site; I knew that a number of other localities were sites; but I did not know all, only a small number. I set the engineers at work on places which I already knew, in order that I might meet a local want at the very earliest day; but still they had in each of those cases to run trial lines, and the money expended in those unnecessary trial lines, if I could have had the topography of the sites which I already knew, would have paid 50 per cent. of the cost of making the map. If I had had a topographic map, even of the sites which I already knew, I could have saved enough in the running of trial lines to have paid 50 per cent., or one-half, of the cost of the map, and that has been demonstrated over and over again on the Arkansas and on other rivers. The greatest waste which I had in that manner was in Nevada. The engineer who went there ran unnecessary trial lines, as the chairman knows. He was the first man to raise an objection to this work; he organized the movement against the topographic work and wasted money in running unnecessary trial lines.

The CHAIRMAN. When an engineer runs his trial lines for his ditch he must be governed by something besides topographic maps, must he not?

Director POWELL. No, sir. Suppose that I have selected the reservoir and the land. That had to be done first. Now I want to know how I am going to get the water from that reservoir to that land.

The CHAIRMAN. Can you select the land before you know definitely where the ditch is to be located?

Director POWELL. I can with a topographic map; otherwise I have got to run trial lines, either one or the other. Without that map I must run trial lines. To make selections by running trial lines is to increase the cost of the work three times.

The **CHAIRMAN**. Can you select with sufficient accuracy to enable people to locate on the lands?

Director **POWELL**. I can.

Senator **MOODY**. In making these topographic maps you run these lines, do you not?

Director **POWELL**. Yes, sir. I run them with plane tables by methods which we have developed in the Survey. To explain it would require a long trigonometrical statement. Let me further say that in addition to the discovery——

Senator **MOODY** (interposing). Right here let me ask, can you run a line with such accuracy as to enable the engineer to follow any line without himself running levels and lines in the usual way, with transit and levels?

Director **POWELL**. Suppose that we have a reservoir at one point, and some land at another point, 10 miles away. I can say from the topographic map that the best line that can be made from that reservoir to that land must run along that hill and meander down that valley, and down that hill, through that valley, to that land——

Senator **MOODY** (interposing). You could do that with the eye.

Director **POWELL**. And having done that the engineer ultimately runs over that ground, and from the reservoir site to the lands for the purpose of doing one other thing. The statute demands that we shall furnish an estimate of the cost. The engineer has to go over the ground and determine the nature of the soil, the nature of the excavations which will be required, what amount of cutting there must be in one place, and what amount of filling in another place, and so on, in order to get at the cost of constructing that canal; but the site of the canal is selected from the map, without any trial lines whatever. I have in my office, Mr. Chairman, three classes of men——

Senator **REAGAN** (interposing). That is the same method that is observed where a preliminary survey of a railroad is made, the details being attended to afterward?

Director **POWELL**. The first thing is to make the selection, as we would in the case of a railroad survey, by trial lines, or by topographic surveying, ultimately selecting one, and then make an accurate survey of it. I have adopted the method of discovering the sites, which is the cheapest of all. But, Mr. Chairman, the topographic work is an important part of the irrigation survey for other reasons than those already explained, and such reasons are even more potent. The amount of water furnished by a hydrographic basin must be discovered. If a reservoir is to be constructed it must be known how much water can be furnished it annually before its size and the character of its works are determined. To select the lands to be irrigated I must know how much water there is to serve and how much water each acre of land will require; that is, the amount of water and the duty of water. In general, there is more land than the water can serve. Only one-eighth or one-tenth of the country can be irrigated, because there is not water enough to irrigate more. I must find out how much water can be got to serve that land. How would I do this? This was the most difficult and complex problem presented to me when the survey was inaugurated. How could we gauge all the rivers, creeks, and brooks of two-fifths of the area of the United States—all the waters flowing in the streams of that region—in order that works for their control and use might be constructed and lands for them to serve might be selected? There is a vast number of these streams, as will be seen by a review of the entire ground. To gauge one stream means what? It means that we have to discover the velocity of the current, which varies from shore to central line and which varies from top to bottom, so it becomes necessary to determine the velocity of the current in every part of the cross-section of the stream, because the flow is not uniform, it being greater in the center and less at sides and bottom, but exceeding variable for different forms of cross-sections. Supposing it to be gauged in this manner on one day of the year, that night a rain falls and the stream is enlarged, the entire conditions are changed, the cross section is larger, and the velocity of the current is greater. So it changes from hour to hour and from day to day, rising with the rains and falling with the drouths.

To find out how much water flows down the stream during the year it is necessary to find out how much water flows in that stream at every stage of its volume, from the lowest water to the highest water. This is done by the use of current meters. Then it is necessary to employ a river-height gauge to determine how high the water is at each hour of trial, and having discovered how much water flows at each stage and how much time it remained at each stage, we are able to determine the total flow of the year. But some years are dry, other years there is great rainfall; so the streams vary from year to year, and their volume in minimum years must be determined, and their maximum volume, and their average volume from year to year. To gauge the flow of each river and brook in the manner which I have indicated would require an enormous outlay of money, so great that when I studied the problem, as I did before the Survey was organized and before it was authorized by Congress, I reached the conclusion that the work could be done in another and cheaper manner, and in a manner altogether more satisfactory. I reached this conclusion after a very careful study of the subject myself and after having submitted it to other gentlemen associated with me. The same conclusion was reached by all the gentlemen except one; that was Captain Dutton. The plan was to make a topographic survey of the catchment basins which should determine with reasonable accuracy their area, with reasonable accuracy their declivities or slopes, and to gauge a few of the streams in the manner which I have indicated and to find therefrom under varying topographic conditions and varying altitudes, and varying rain-falls, the amount of water which could be derived from each square mile of the territory of the basin.

Permit me to make this plain by the use of an illustration which will serve well for that purpose and better than a long discussion of the subject by which the scientific methods might be elaborated. Suppose I wish to know how much water there is running annually from the roofs of the houses of Washington. Shall I put a water-spout on every roof and gauge each one for every day in the year and for a series of years in order to get the mean annual flow ? Such was the plan advocated by some ot the engineers, but such was not the plan adopted by myself. Now suppose I gauge the amount of water which falls from the roofs of a dozen houses in Washington, or even a less number, so as to get a good fair average of what every square yard of roof surface will deliver during the year. I can then easily determine how much water a square yard of roof surface will furnish during a year; and having found that a yard of surface, for example, on a general average, will furnish a yard of water 30 inches in depth during a year, I have the means of determining the amount of water which any roof in the city will afford by simply measuring that roof. This is certainly a very much simpler and just as satisfactory a method as to put a current-gauge on every water spout of the city. To do the work of the survey by gauging all the streams would cost an unknown sum, but certainly not less than $10,000,000. So I determined to gauge a few typical streams and measure their catchment areas; that is, to determine the extent of catchment area and to base the computations of water supply upon the factors thus developed and upon the factors derived from the measurement of rain-fall. But it is necessary not only to measure the superficial area of the catchment basin, but also to determine the declivity or slopes of the ground by which the water would be gathered into streams and delivered to the irrigating works. The necessity for determining this element can be very simply explained.

The CHAIRMAN. The hydrographic survey is different from the topographic, to some extent, is it not?

Director POWELL. No, sir. A hydrographic survey is a topographic survey, but something more is added. A hydrographic survey determines the areas by a topographic survey. I was trying to explain that in my illustration of the roofs of the houses. I have to measure the roofs of the houses, from which the area of the roofs, the catchment area, is determined. It is the method of determining the areas which supply these basins. But there is another thing——

The CHAIRMAN (interposing). You have to approximate the area of the basin, do you not?

Director POWELL. It is not sufficient to approximate the area. It is necessary to determine the declivities. That is a problem which seems very simple when it is stated; but you will find that we have to determine the slopes of all the hills for the purpose. Suppose the rain falls over a district of country that is level, or nearly level; in that arid region no great quantity of that water will flow into a reservoir. It will be gathered up so slowly into pools that it will all evaporate. But suppose it is like that of the Hassayampa, of which the dam has just been swept away. Then all the water which falls upon the catchment area, after the soil is once saturated, will immediately be gathered into the reservoir. It is a region of steep declivities. Here is the source [indicating on the map]. Here is Mount Tritle; here are four great mountains encircling the basin. When a great storm comes on those mountains the water rolls down into the basin. They sometimes have storms in that western country which will give 2 inches of rain-fall in two or three hours. The Hassayampa dam drained a mountain declivity of 325 square miles of nearly naked rock. When the big storm came it only required seven or eight hours by my computation to bring the maximum supply of water against that dam. The maximum supply of water against that dam was 6¼ acre feet per second. There was that much water coming down every second for nearly an hour. Provision had to be made for it, and the declivity had to be known in order to construct the work properly. It was not only necessary to provide a proper way to dispose of the surplus water when it came, but also to know how much water could be stored there. If it had been a flat country there would have been no need to make a dam there, for no water would come down; but it being a steep country, a vast amount of water could be collected.

Now to make my illustration from housetops complete, suppose that the flat housetop is covered with a great thickness of sand, so that all the rains falling thereon are absorbed and finally evaporated by the sun. Then from such tops no water can be caught in the spouts. Suppose that others have varying declivities, and that the greater the declivity the less the amount of sand, until some are so steep that no sand will remain on them. The steep roofs will deliver all their water. Now similar conditions are found in the natural slopes of every drainage basin of the West. Some regions are so flat and sandy that the waters all evaporate, and nothing can be obtained from them; others are so steep and rocky that almost the entire rain fall is discharged into stream-channels. It is wholly a question of declivities, and we are therefore compelled to determine these declivities. We want areas of catchment basins and declivities of catchment basins. To get these we make a topographic survey, in the cheapest manner that it can be done to be useful to properly solve the problems. The plan, therefore, is to measure drainage basins and determine their areas and declivities, to see what water they will shed in the streams; then gauge a few typical streams with accuracy, and with these facts—and some collateral ones which need not be here explained, as that would complicate the subject too much for simple statement—we have the data necessary to plan the works to control the water, so that it can be put upon the land.

The CHAIRMAN. I have heard it suggested by engineers that in some portions of that arid region there are places where no dam could be safely built, and that those places would be generally indicated by the large bowlders and rocks at the mouths of the cañons, showing that water-spouts had come down with such force as to carry those bowlders through the cañons; and I have heard it suggested—and I want to know what there is in that suggestion—that they would have to avoid those places because of the evidences that water-spouts are likely to occur there. I have also heard it suggested that a good engineer in constructing a dam on those torrential streams would always leave a sufficient waste-way to carry the whole body of water at flood-time, that there should be an ample allowance, so that there would be as large a water-way as there was before the dam was constructed, and that on the ground many things besides the declivities had to be taken into consideration.

Director POWELL. In the first place, as to water-spouts. I hold that the suggestion which they make about water-spouts is valueless. You might as well say you will find the places where lightning has struck and will not build houses in such spots. The distribution of water-spouts is now here and now there. I mean by "water-spouts," tornadoes. Their distribution is not controlled chiefly by the topography of the ground, but by movements in great bodies of air more or less loaded with vapor.

The CHAIRMAN. Now, let me make a suggestion. At Eureka and Panamint Cañons, the former of which has been known about twenty years, there are bald mountains above, where clouds meet and cause these cloud-bursts or water-spouts. In Eureka Cañon the town has been destroyed once or twice, and they have had to build back on the hills to get away from the floods. There have been four or five water-spouts or cloud-bursts in that same place. Panamint Cañon has not been known so long, but there is a similar formation there—bald mountains, the tops of which are very high. Large bowlders have been carried down and land-slides have been produced by these cloud-bursts. We know from observation that they have appeared periodically and that they are liable to occur again; that there are a great many places where they have repeated themselves.

Director POWELL. Let me make an explanation, Mr. Chairman. A tornado is one thing; what is usually called in the West a cloud-burst is another thing. The term "cloud-burst" does not mean anything, really, to a scientific man except a big storm. Those occur in all lands, but they are peculiarly destructive and remarkable under the conditions you have suggested. We have just as many cloud-bursts in Washington as they have at Eureka or Denver. Let me explain further. Suppose there is a region of country the declivities of which will gather all the water that falls during a great storm suddenly; instead of days, it gathers in hours or minutes, as is the case at Denver. If the declivities are extreme and a great storm comes, the people call that a cloud-burst.

The CHAIRMAN. I have seen a great many of them. I have been in the sunshine, and have seen a dark cloud off over the mountains, accompanied by thunder and lightning, and have seen the people running to the mountains to escape what was inevitable, because they knew the place so well, and in half an hour the water would be 25 feet deep where they had been. The friction of the water on the bottom of the stream would make a column of water that was almost perpendicular; a wonderful sight.

Director POWELL. I have walked before such a one, where a wall of water nearly as high as my head came down a dry stream bed. The region of country most affected by those sudden storms on the face of the globe is the region which I first explored, that of the Colorado River. There the walls of the cañons are from 4,000 to 6,000 feet high, with a labyrinth of cañons running into it from either side. When the rain falls in that district of country the Colorado River is raised, sometimes many feet in one night. The great storms which occur at the headwaters of the river do not fill the cañon as full as the local storms do, because in the local storms the water falls on the declivities, which are like the roof of a house, and is discharged into the river in a few hours.

The CHAIRMAN. Would it be safe to build dams in those peculiar cañons at all?

Director POWELL. I think not. I am afraid the line of my thought is so broken that——

The CHAIRMAN (interposing). I will not interrupt you again.

Director POWELL. I am very glad to have you ask questions. I wanted to say that the topographic map, then, is the chief expense of the hydrographic survey, as the measurement of the roofs of the houses of Washington, which I used as an illustration, would be the chief expense of determining the rain-fall. My hydrographic survey is primarily a topographic survey. The selection survey is a topographic survey. I have to determine catchment areas, reservoir sites, and irrigable lands, and I have to determine the sites of diverting dams and lines of canals. All these are done by the topographical survey, and, in my judgment, in the cheapest possible manner.

Adjourned.

SEVENTH DAY'S SESSION.

WASHINGTON, D. C., *March* 18, 1890.

The committee met pursuant to adjournment.

Present: Mr. Stewart (chairman), Mr. Plumb, Mr. Moody, Mr. Casey, and Mr. Reagan.

FURTHER STATEMENT OF DIRECTOR POWELL.

The CHAIRMAN. Major, you can proceed.

Director POWELL. I attempted at the last meeting to explain the use of the topographic survey in carrying out the purposes of the statute in making the irrigation survey. The things which, under the law, we are compelled to discover are, first, the catchment areas and their declivities, in order that the amount of water can be determined and the method by which that water can be controlled and brought upon the land. It was shown that we not only need the area of the catchment basin, but its declivities, and the topographic survey economically discovers the area and the declivities. The higher declivities are determined in a more general way than the lower ones. The regions of the reservoirs, of the canals, and of the irrigable lands are surveyed topographically with a great deal more refinement than the others. We also have to discover the sites of the reservoirs, and, as I believe, of all practicable reservoir sites, for the purpose of selecting those which are best and most economic, and which serve the lands the best. The second purpose is to discover the sites of diverting dams along the streams, or service dams, as they are sometimes called, and the sites of canals. For this purpose, as there are a great many canal sites to be discovered in any one district, it is necessary to overlook the entire district in order that the best may be found and selected. Having discovered all possible reservoir sites, all possible diverting-dam sites, all possible canal sites, and all possible lands that can be irrigated, it becomes necessary, then, in view of all the facts, so that they may be correlated one to another, to make selections. The discovery of these by the use of trial lines, I stated, would cost at least three times as much as to discover them by topographic methods. They must be discovered by some method or other, and for the purpose of discovering them the most economic method is used. Further than that, it is necessary to determine the volume of water flowing in the streams, and for this purpose it is found, after a careful examination, that this stream-flow can be discovered by a combination of topographic and gauging methods with very much greater economy, and I illustrated that by showing how we would discover the amount of rain which could be gathered from the roofs of a city. I suppose that the hydrographic survey, if we had attempted to gauge each stream, would have cost from four to ten times more than by the present method; so that, altogether, the use of the topographic survey for discovering all these facts in relation to the hydrography—the reservoir sites, the canal sites, and the irrigable lands—very greatly reduced the cost of the work.

Senator MOODY. Will you please describe how you execute this topographic survey for such a purpose?

Director POWELL. Yes, sir; in the first place, we enter a hydrographic basin—we will speak of one basin, as that will illustrate them all.

Senator MOODY. Just select some place.

Director POWELL. I will take the Upper Arkansas, for example. There we measure a base line——

Senator MOODY (interposing). Did you carry on any topographic work there during this last year?

Director POWELL. Yes, sir.

Senator MOODY. Whereabouts?

Director POWELL. Through the basin, from the summit of the mountains in Colorado nearly down to the Kansas line, so that we have covered almost all of the Arkansas basin within the arid region.

Senator MOODY. In this connection, did you have any engineering work done outside of the topographic work?

Director POWELL. Yes, sir.

Senator MOODY. What was that?

Director POWELL. That was to measure the capacity of the reservoir sites, to make plans for dams, and the construction of reservoirs, to run lines of canals on the ground, and estimate their cost. That was the engineering part of the work.

Senator MOODY. How did the topographic work aid that engineering work?

Director POWELL. The topographic work practically discovered all of the reservoir sites and all the canal sites. It also discovered the hydrographic basin—the outline of the hydrographic basin and its slopes.

Senator MOODY. Please give in detail, if you will, the manner of executing that topographic work at one single point where you discovered reservoir sites.

Director POWELL. A base line is measured. From that base line a system of triangulation is projected, which is exceedingly inexpensive, costing, perhaps, at the rate of fifteen cents per square mile. That covers the basin with known points with far more accuracy than it could be measured with chains at a hundred times the cost. Then the topographer determines, at the bottom of the basin its altitude above the level of the sea. He proceeds up the main stream and up its lateral branches with a line of levels, so as to determine the gradients of the streams themselves. As he proceeds in this way up the stream and up the lateral streams, he locates himself from point to point by the known points which are already established by the system of triangulation, stops at this point or that point and finds out where he is at the moment, and plots that upon a plane table which he carries with him. From his station then with gradienters in part and alidades in part, and with other instruments, he determines the altitude of the hills and valleys about him and makes a map of the region on the ground then and there, passing from point to point along the streams, as I have mentioned.

Senator MOODY. What becomes of that map? Does he turn it over to the engineers, so that they can measure and determine the capacity of this basin?

Director POWELL. Ultimately with all the data gathered in its construction. As he goes along he runs grade curves in the valleys, in some places 10 feet apart, but in general in the valleys where irrigable lands are situated the grade curves are run 20 feet apart. Higher up in the mountains they are run 50, 100, or 200 feet apart. It is not necessary to do the work with a great degree of refinement in the mountain regions. Thus he constructs a map as he goes of that drainage basin. When that map is constructed he is enabled to outline upon the map, first, the area and declivities of the drainage basin, and, second, all possible reservoir sites—the topographer has discovered them—all possible irrigable lands, and all lines of canals from the reservoir sites and the streams to these irrigable lands.

Senator MOODY. Does he form one of a general party, including the engineers, who are running the actual levels and laying out lines?

Director POWELL. No, sir. The work is carried on by three parties—one a topographic party, one a hydrographic party, and one which is working upon the lines and canal sites, making plans and estimating cost of construction. Those are three different functions, which are pursued by three different classes of men. Shall I go on further with an explanation of how the maps are made?

Senator MOODY. Yes; until you show the connection between the topographic work and the engineering and hydrographic work.

Director POWELL. The topographers having discovered the reservoir sites, the canal sites, the irrigable lands, and the basins that are drained, the material is furnished to the engineers and hydrographers. The hydrographers do not go with the topographers, but we select in such a basin some point where one or two typical streams can be gauged, and the hydrographer stops at that station and measures the stream from time to time until he has determined the volume of water flowing in the stream at its various stages. Then he selects a series of points on a series of streams and arranges his instruments in such a way that he passes from one stream to another, visiting them once a day, once a week, or once a fortnight, as the case may be, having stationary instruments which record automatically for a part of the work. Finally the hydrographer has discovered the flow of the stream, and from an examination of the topographic maps which have been prepared, which give areas and declivities, he is able to say what water can be furnished for irrigation and what works are necessary to control it. Having these facts and the sites discovered and the lines discovered, the engineer now enters upon his duty, and he decides that out of fifty reservoir sites twenty of them, perhaps, are the best. Having determined that these twenty reservoir sites are good, having marked the general routes or lines of the canals which must be constructed from these reservoir sites to the lands to be irrigated, he then runs upon the ground the lines necessary to outline the basin with accuracy, cross-sections it to determine exactly how much water it will hold, he then examines the site for the dam, and determines its foundation, length, and height. Having these factors before him—the amount of water which can be supplied to that reservoir and the amount of water which in great storms it must be able to control so as not to be destroyed, all of which is furnished him by the topographers and by the hydrographers,—the engineer's duty now is to plan the works, mark their sites upon the ground, and estimate the cost of their construction.

Senator MOODY. Out of the appropriation of $250,000 how much was assigned to topography?

Director POWELL. About one-half—nearly one-half.

Senator MOODY. And how much to the engineering and hydrographic work?

Director POWELL. The other part—a little bit more than one-half.

Senator MOODY. Can you give the exact amount?

Director POWELL. I can not from memory, but I think, perhaps, I have the data here.

Senator MOODY. How much of the topographic assignment has been expended?

Director POWELL. About seven-eighths of each.

Senator Moody. That is, seven-eighths of $350,000?

Director Powell. Seven-eights of the part of the $350,000 which was assigned to topography. I have laid all those facts before this committee heretofore. In the statement I made some time ago I gave the cost per square mile, etc., as you will remember. That is all in my testimony.

Senator Reagan. One of the points made against this topographic survey is that you have assigned a great deal more money to that than to the hydrographic survey and the engineering work, and that you are making it cost more than it ought. I wish you would let us know how that is.

Doctor Powell. The engineering work of marking on the grounds the lines discovered by the topographic survey and the sites of the reservoirs and the computation of the cost of the work will, I suppose, require about three-fourteenths of the appropriation.

Senator Moody. That would be about $60,000.

Director Powell. Yes, sir; of the last appropriation of $250,000. A larger proportion was used this year because we had not the topography in every locality; but I am speaking of what the plan will be in the future. All this has been set forth to the Appropriation Committee of the House, and is on record. The hydrography will cost, if carried on by our present plan, about three-fourteenths, and the topography, as it is called, will cost eight-fourteenths of the money. That is about the proportion which it will be in the future. That has not been the proportion this year. We chanced this year to know of certain reservoir sites from previous studies of the country. These were already known, and we did not have to go to the expense of discovering them.

Senator Reagan. While you are on this branch of the subject I wish to present a point which I think will be of interest to the committee. It is alleged that by your plan of a topographic survey it will take many years to complete with a very large expenditure. I have heard the suggestion made before the committee that the cost will be $ 10,000,000, and that it will greatly delay the development of the project of irrigation. I would like to know what you have to say to that.

Director Powell. To complete the survey of the arid region, which is about 1,300,000 square miles, and which does not include the subhumid region where some irrigation is practiced, will cost $7,000,000 by following the methods which have been adopted. The time in which it can be completed will depend upon the rate of appropriations. If appropriations are made at the rate of $250,000 per year it will take twenty-seven years; if made at the rate of $1,000,000 per year, as I have recommended to Congress, it will take seven years. But if the methods which we have adopted are abandoned and the more expensive and less satisfactory methods are adopted, it will take five times that amount of money; and if the rate of appropriations should remain the same it will take five times as long. I have explained to the Appropriations Committee, and my statement is on record and I have it with me, that the topographic branch of the work will cost $4,000,000 in addition to what had been accomplished prior to the commencement of the present fiscal year; that the hydrographic survey, as I have planned it, will cost an additional sum of $1,500,000; and that the engineering survey will cost another $1,500,000, making in all $7,000,000.

Senator Reagan. What is it that will cost $4,000,000?

Director Powell. The completion of the topographic branch of the irrigation survey for the arid region, not including the subhumid region, for which no estimates have ever been made, will cost $4,000,000 more for the construction of the maps; but in the construction of the maps we discover all reservoir sites, all canal sites, all drainage basins, and also discover by the same method the data upon which we determine the amount of water which each basin will supply. That will cost for that region $4,000,000. The experience of this year shows that that was a liberal estimate. It was based upon the theory, as explained to the committee, that it would cost from $4 to $5 a square mile. The work this year has cost $3.78 a square mile, and that will carry us to the 1st of July and complete the office work; so that the estimate was not too small, but was quite within bounds. Then I estimated to the committee that it would cost $1,500,000 more to segregate the lands; that is, to run all township and section lines and discover, in Land Office terms, what lands should be segregated, so that we could report to the Land Office the particular lands which are selected under the law. The law compels us to segregate them. The measuring of the reservoir sites and the computation of the cost of works—all this for $1,500,000 more. Then $1,500,000 for the gauging of streams and the work of the hydrographic branch; which makes $7,000,000; $4,000,000 for the discovery of the facts——

Senator MOODY (interposing). That is the topographic work?

Director POWELL. Yes, sir; and $3,000,000 for the other.

Senator MOODY. For the engineering work?

Director POWELL. For the engineering and hydrographic work and segregations.

The CHAIRMAN. As I understand you, the topographic work precedes and is independent of the engineering work, and the engineers simply use the maps prepared by the topographers and obtain the information as to the flow of water from the hydrographers and then they proceed afterward?

Director POWELL. Yes, sir.

The CHAIRMAN. What connection is there between the topographic work and engineering work? Are the two classes of work done by separate forces or by the same force; that is, is the work done by separate divisions or one division? Do the engineers simply take the maps from the topographers when they are done and go on with their work alone?

Director POWELL. The engineers take the data which the topographers have prepared for them. They do not go over the ground to discover reservoir sites, they do not go over the ground to discover canal sites, they do not go over the ground to discover irrigable lands, they do not go over the ground to discover drainage basins or catchment areas. All these facts are determined for them, and they go to the reservoir sites, the canal sites, and the dam sites, and make their estimates of what it will cost to do the work, how the reservoir, the canal, and the dam shall be constructed, and what it will cost. That is the duty of the engineers.

The CHAIRMAN. Will the topography furnish them with data accurate enough to enable them to locate the reservoir sites and the canals without running over the ground with transit and level?

Director POWELL. Yes, sir; except on the lines selected, as I have explained to the committee. The reservoir sites themselves have to have a much more accurate survey, and the line which is selected to take the water from a reservoir site to the land has to have a much more accurate survey.

The CHAIRMAN. What is to hinder the engineer from going upon the ground and locating his reservoir site without the aid of topography? For instance, I go up into the mountains, and I find a stream of water; I follow that stream up, and I find upon it various flat places, without any engineering at all, and I can see with the eye that I can build a dam there. Then I find that an area of country below in the valley is irrigable. What is to prevent an engineer from first ascertaining about where the water could be taken out at the foot of the mountain, and determining what lands he could irrigate with his level, and without running any trial lines, and then going on up the stream and locating his dam site? After he has determined the location, he has used his level, and has the topographic part done. Why can he not do that without any previous topography—diagnose the stream, as it were, and construct his dam?

Director POWELL. I will explain that. I can make that clear. Here is a stream coming down from the mountain. We wish to store the water from that stream. We might go along that stream and dam the stream itself, and make reservoirs along its course; but when it is possible to avoid it, we never do that. We never build a reservoir on the course of the stream if it is possible to locate it anywhere else.

The CHAIRMAN. That is if it is a rapid stream?

Director POWELL. No matter what kind of a stream it is. To store the water upon the stream itself is to store it where the works have got to be constructed in such a manner that they will withstand the greatest storms. Wherever it is possible, and we find largely that it is possible, we store the water outside of the bed of the stream, making a low diverting overflow dam in the stream itself, and throw the water out on the mesa or valley to one side, so that a torrent coming down the stream can not destroy that reservoir; and the question you ask brings out one of the most interesting things relating to the subject of the storage of water—that is, never to build a reservoir upon the course of a stream when another site can be found. If you wish to construct a reservoir to store the water of a stream of great volume, take the water out by a diverting dam and a lateral canal, and store it in a basin on one side.

The CHAIRMAN. That our miners learned forty years ago in California; I among the rest. We found we could not make our storage reservoirs in the streams without great dams, and the water was diverted through ditches to storage reservoirs, built sometimes right above the placers or on the top of a knoll by throwing up banks around it, always where it would be protected from the floods. That has been the experience in the mining regions. Now, the engineer is a pretty good judge of what can be done in a torrential stream without any topography. I recognize, Major, the convenience in entering into a district of having the topography in advance, because you know then where to go to work, but I do not see so forcibly its practical necessity.

Director POWELL. Mr. Chairman, it is necessary for somebody to see all of that ground before the plan is made; somebody must see it. The engineer must see it, or somebody must see it for him. He must not only see it with his eye, but he must see it instrumentally. No man can properly estimate distances, altitudes, and slopes without instrumentation. Having seen it instrumentally, all that is needed after that is to put it on paper, and if he puts his notes on paper, makes a record and keeps a note-book, it takes just about as long as it does to make a map. The map is all made on the ground right then and there. The map is a note-book, the simplest and cheapest method of keeping the records. There it assembles the facts so that they can be seen as a conspectus and their relations known.

Senator MOODY. What is the difference between the topographic work done under the specific appropriation for topography and the topography connected with irrigation which you have carried on?

Director **Powell**. To the topography which we ordinarily do is added for irrigation a more careful determination of the declivities or gradients of the streams; that is all.

Senator **Plumb**. Is the topographic survey which you have been making from the Geological Survey appropriations suitable for the Irrigation Survey?

Director **Powell**. Yes, sir; except on one point; the gradients of the streams are not so carefully determined——

Senator **Plumb** (interposing). What is it suitable for without this addition you speak of?

Director **Powell**. For all purposes for which maps are used.

Senator **Plumb**. Then all the work you have done for the geological survey of a topographic character, in order to make it adaptable to irrigation has got to be supplemented by something else?

Director **Powell**. Yes, sir; but at a cost which is insignificant. Not over 3 cents a mile is to be added to what has been done.

Senator **Plumb**. Then you have been doing under this last appropriation practically what you were doing before?

Director **Powell**. So far as the topographic work is concerned; but we have added to that the gradients of the streams. The organization of the Geological Survey, prior to the foundation of the Irrigation Survey, provided that the Geological Survey should make a map of that country. When that map was authorized by Congress a statement was made by me—and the joint committee of the two houses has reported fully on the matter, and I have the report here—that it would take, at the rate at which appropriations were then in progress, thirty years to make that topographic map. When I presented the matter of the use of that topographic map to the committee I explained its importance, its value, for irrigating purposes, and the commission have reported upon that pretty fully, as you will see from a report which I have brought with me. When the matter of the irrigation survey itself was brought before Congress, session before last, I first was called upon, by a resolution of the Senate, to reply to certain interrogatories as to how this irrigation survey should be conducted, and I outlined in my report to Congress just what I have been doing and what I have explained to the committee, and my report has been published by Congress. I explained the use of a topographic map in relation to an irrigation survey as I had explained it years before, and appearing before the Committee on Appropriations to explain what would be done, I said to them that we would have to add something to what we have been doing for the purposes of estimating the cost and segregating the lands; and if appropriations could be made in such a manner that the time of the work could be shortened, and something more added to that—I said a million and a half for the hydrographic work and a million and a half for the engineering work—I said if $3,000,000 be added to the general estimate heretofore made, we can do the whole work, for we are already doing at this slow rate the topographic work necessary; and the committee on considering the matter understood very well—in their report you will see that it was understood—that they were anticipating the appropriation, that is, making larger appropriations to do what was already authorized, and in addition to that, making an additional appropriation to do these additional things. That was understood clearly by the Committee on Appropriations, and is all a matter of record. The topographic survey, therefore, is necessary, or something to take its place. If the trial-line system is to take its place, the total cost of the whole survey will be increased five times. The total cost of the discovery of sites only—that is, a part of it—will be increased three times, but the total cost of the whole survey will be increased five times; and then the topographic map will still have to be made for the Geological Survey.

It must be understood in this connection that I have submitted to Congress a plan for an irrigation survey of the arid lands, which contemplated an examination of the subject only so far as it related to the use of perennial streams; that it was not contemplated to make a survey relating to artesian waters, storm waters, or sand reservoir waters. If the scope of the survey is to be enlarged the estimates must be correspondingly enlarged. It should be further noticed that the estimate was made for the arid lands where irrigation is generally necessary, and not for the sub-humid lands where irrigation is necessary only in unusually dry years. If the survey is to be carried over these sub-humid lands the estimate must be correspondingly enlarged.

Now, gentlemen, the hour is nearly up, and I have hardly started on the subject; but I wish to beg of you one favor in this matter. You have heard two men connected with the Geological Survey who disagree with me, whose opinions are not my opinions.

Senator PLUMB. Who are they?

The CHAIRMAN. Captain Dutton and Mr. Nettleton.

Director POWELL. I have a good many men on the Survey. The men who are actually responsible for selecting the sites entirely disagree with the men who have appeared before your committee, and agree with me, and I want to beg of the committee to hear both sides of this question, and if you are going to interrogate me and my assistants, let those assistants be heard. Mr. Gilbert, who is practically the assistant director of the Survey, who has been associated with me for sixteen years in this work, and who joined me in the first report on the question of irrigation, has a better mastery of this subject, probably, than any other man in the country. Mr. Thompson, who has been with me twenty-one years in all the work, and who has charge of the map-making, is another whom I would like to have appear before you. I should like to have you call Mr. Gilbert, Mr. Thompson, Mr. Gannett, and Mr. Johnson, all of whom have thoroughly studied this subject, and know how to make maps and how to explain them, and are familiar with all branches of this work.

The gentlemen in charge of parties in each branch of the work have a tendency to exalt the importance of the special branch which they themselves are pursuing, and are apt to claim that the bulk of the appropriation should be given to them for their work. They are anxious to accomplish as much as possible, and to do it in the best possible manner, and urge their claims in what I think to be a very proper manner. I am not sorry that my assistants thus become interested in the work; but it is for me to co-ordinate it and to relegate to each branch its due and proportionate part. This is the error which I think Captain Dutton has committed. The magnitude of the work which he performs and its immediate presence before his eyes obscure his vision, and he fails to discover the magnitude and importance of the co-ordinate branches.

The CHAIRMAN. Could they not make their statements in writing?

Director POWELL. If so desired.

The CHAIRMAN. Have them make their statements in writing, and present them to the committee as soon as possible. We are occupying a great deal of time, and want to consider some other matters, and if the gentlemen you have named can make their statements in writing it will expedite matters.

Director POWELL. You sought the opinions of two men who never made a topographic map——

Senator JONES. (Interposing.) It seems to me like a one-sided affair to allow men on one side of this question to come here and answer questions, and now to have the men on the other side put their statements in writing, without giving the committee an opportunity to ask them questions. It is not right. I want to get the whole truth.

The CHAIRMAN. If there is objection to the written statements of course we will have the gentlemen come before the committee.

Director POWELL. I have been diverted from my line of thought by side interrogatories, and I would like to be heard further. The things which I intended to present are not presented yet.

The CHAIRMAN. We will have another meeting as soon as we can get the committee together.

Adjourned.

EIGHTH DAY'S SESSION.

Washington, D. C., March 21, 1890.

The committee met at 10.30 o'clock a. m.

Present: The chairman, and Senators Reagan, Moody, and Casey.

STATEMENT OF G. K. GILBERT, CHIEF GEOLOGIST OF THE U. S. GEOLOGICAL SURVEY.

Mr. GILBERT. Is it your desire that I make a statement, or that I shall answer some specific questions?

The CHAIRMAN. The committee desire to ascertain from you your opinion as to the connection between the engineering survey for the purpose of irrigation and the topographic survey, and whether the topographic survey is a necessity and must precede the engineering survey. You can go on and make a statement on that subject, giving the relation of the two surveys, the dependence of one upon the other.

Mr. GILBERT. It is my opinion that the information obtained by the topographic survey is essential to good results from the engineering survey. If the same information is obtained by other methods the cost will be relatively great; if it is not obtained the engineering survey will fail to achieve the best results. The topographic survey should precede in each locality.

The function of the irrigation survey, as a whole, is three-fold, as determined by the law. It has first to determine what land shall receive the scant water of irrigation; second, to plan the best system of works for distributing the water to the land, and third, to plan the best system of reservoirs for storing the water which falls in a drainage basin outside the period of irrigation. For each locality, for each drainage basin, as a rule, these three questions have to be considered together. They are so intimately related that they constitute a single complex question, which has to be determined for each locality; nevertheless each one of the questions is in itself complex.

In order to make the best selection of land it is necessary to know what tracts of land are available for the purpose of irrigation; that is, what tracts of land belonging to a district lie so level that the water can be conducted over them for the purpose of irrigation, and what are the areas of these tracts. It is necessary in selecting from among such tracts to consider their climatic conditions; in some cases there are great differences in climate. It is necessary to consider the soils and subsoils. It is necessary to consider the local duty of the water. It is necessary to consider the waste of water incident to transfer from the source of supply, that is, the distance from the source of supply with reference to the question of waste; and it is necessary also to know the amount of water which is available for some one or more of these districts, that is to say, the annual run-off of the drainage basin. In order to plan the best system of distribution it is necessary to know the positions of the tracts of land which may be irrigated with reference to the reservoirs in which the water for that purpose may be stored. These relations must be known horizontally and vertically, and the character of the intervening country must be known. It is necessary also to estimate the cost of constructing works for distributing the water, and the cost of maintaining such works. It is necessary to estimate the waste through evaporation and seepage by different systems of work, and it is necessary, in order to determine the magnitude of the works, to know the run off of the basin.

Speaking in a very general way, a reservoir can be made anywhere; but there is a great difference in expense, and the really available or practicable sites are those where a relatively small dam will create a reservoir containing a relatively large amount of water, and such sites may be scattered throughout the basin. In determining the question of reservoir sites it is necessary usually to consider whether there shall be a single reservoir or a small number of reservoirs low down in the basin or a larger number of reservoirs on the minor streams pertaining to parts of the basin. In order to make a comparison of these and to plan the best system of works it is necessary to estimate the cost of works, at least roughly, at the various places, and the cost of maintenance, and to consider the waste through evaporation or seepage; these differ with altitude and other conditions, and also with the form of the reservoir. It is also necessary for the other purposes; that is to say, where a reservoir site commands only a portion of the basin, the water which can be stored in that reservoir is only the water which flows through or past that portion of the basin. So, for the study of the problem of reservoir sites it is necessary to estimate with a good degree of approximation not only the run-off of the entire basin, but the run-off of parts of the basin.

Now, in this plexus of factors there is one which is very important; many of them are important, but there is one that is especially important and which is at the same time especially difficult; that is, estimating and determining the run-off. That may be determined, theoretically, at least, in various ways. In the first place, it can be measured directly; the streams can be gauged and their heights at various times can be observed for a period of years, and in that way the amount of water which runs off can be actually measured. For large streams the observations of one year give valuable information; the observations of two years may perhaps suffice for some purposes; but for small streams, in a region of very irregular precipitation, a greater number of years of observation is necessary. There are certain things besides the average annual run-off that need to be known. With reference to the determination of the amount of land it is advisable to put under ditch, the minimum run-off should be known. With reference to the construction of head-works and canals and dams that will stand against all floods that may come, it is necessary to know the maximum run-off, and it is especially necessary to know the maximum rate of run-off for this purpose. It is necessary to know separately the run-off of each stream that may be separately used in irrigation, and it is necessary to know separately the run-off of each catchment area the water of which may be separately stored.

The direct measurement of the run-off is, in my judgment, a very expensive matter. There must first be determined by a series of gaugings how much water runs off at each stage, and observations of the height of water must then be made and recorded for a series of years. For this purpose it is necessary to keep permanent observers, and such observers can not maintain continuous observations of any considerable number of streams. In my judgment the expense would be not far from $1,000 for each such determination, carrying it on for a sufficient number of years to make it of practical value.

Senator CASEY. What would you consider a sufficient number of years to make it of value?

Mr. GILBERT. That would depend upon the size of the stream.

Senator CASEY. Well, generally.

Mr. GILBERT. I think on an average three or four years would be necessary; but that would not suffice for a great number of small streams. In the case of large streams you could——

Senator CASEY (interposing). Would observations for three or four years determine the maximum and minimum?

Mr. GILBERT. No, sir; not in small streams. In the average run of streams the maximum and minimum occur only at irregular intervals, which may be short or long. That would be a matter more or less of estimation, even after a long series of observations.

Senator CASEY. You spoke of it as necessary a while ago.

Mr. GILBERT. It is important. It is necessary to determine the best works.

Senator CASEY. That would probably take eight or ten years' observation?

Mr. GILBERT. Yes, sir; it would bring the cost into competition with the gain to be acquired through the irrigation of the land.

The CHAIRMAN. It is now twenty-nine years since there was a winter similar to this last winter in California and the country west of the Rocky Mountains.

Senator CASEY. Does that remark go back to last summer and include the whole year?

The CHAIRMAN. Yes, sir; it includes the whole year. There was a very dry year twenty-nine years ago, 1861–'62, and this is 1889–'90.

Senator CASEY. So that if this information as to maximum and minimum run-off were ascertained, it would take a long series of observations?

The CHAIRMAN. What is the difficulty in allowing the inhabitants or inducing them to keep a sufficiently accurate gauge of the water for practical purposes? Could not some arrangement be made with the people living in that region to keep a record which would be sufficiently accurate?

Mr. GILBERT. That is the practical method of ascertaining the greater part of the run-off—to gauge the streams through experts and then employ local observers to watch the rise and fall. That is applicable only to the districts that are actually occupied by settlers now. There are great unsettled regions where the run-off would have to be determined in order to construct the best works, and these would have to be occupied——

The **CHAIRMAN** (interposing). Take, for example, the districts in Nevada that are actually occupied; are they not index localities that will do for the unoccupied districts?

Mr. **GILBERT**. I think so. I was coming to that——

The **CHAIRMAN** (interposing). So that the Government would not have to go to the expense?

Mr. **GILBERT**. I was speaking of the method of gauging the water in the streams. That method leads to large expense, in my judgment. The number of measurements that would have to be made in order to consider thoroughly the whole problem of land areas and of reservoir sites would be as much as twenty thousand, leading to an expense that would go into the tens of millions. Now, there are several indirect methods of reaching the result, and I would like to speak of three of these. In the first place, it is possible, usually, by an examination on the ground, to determine what is the magnitude of the flood channel of a stream, and then, by considering the cross-section of the channel in connection with its declivity, it is possible to estimate the rate of the maximum discharge.

The **CHAIRMAN**. An engineer can do that?

Mr. **GILBERT**. Yes, sir; and every one makes a crude estimate. When one sees a place where water has run, he thinks "Some time here has been a large stream." The engineer can measure the gradient and the cross-section, and can give an estimate of the rate of run-off in the time of the most severe storm, which will be valuable. In a humid region the rate of run-off is well related to the annual discharge. If we were dealing with a humid region instead of an arid region we might, by a consideration of the magnitude of the storm channels, make an estimate of the annual discharge which would be really valuable; but in the arid region the precipitation is so irregular that this is impossible. I have crossed on the Amagosa Desert a river-bed that is a mile broad. There was no water when I crossed it, and had probably been no water for many years, but at some time there was a great stream; yet that channel runs into Death Valley, and there is not enough water flowing through it annually on an average to keep the bottom of Death Valley wet.

The **CHAIRMAN**. I have been there.

Mr. **GILBERT**. So the study of channels in the arid region will not suffice for the determination of the annual run-off of the streams. Another indirect method is by analyzing the features that go to make up run-off, and then measuring the factors and putting them together by computation. We know that the run-off depends, in the first place, on the rain-fall. Now, if we can tell what percentage of the rain-fall escapes, and measure the rain-fall, we have our problem solved. The quantity that escapes depends particularly on two things—the declivity of the surface, or the rapidity with which the water runs, and the constitution of the surface or the soil. Some soils shed water; others hold it and yield it to evaporation.

Senator **REAGAN**. Now, this is all very interesting; but it is not the point we are trying to get at at all. We want to know, as I understand it, whether a topographic survey is necessary as a means of providing an irrigation system, or whether that can be done more cheaply and quickly by an engineering and hydrographic survey.

Mr. **GILBERT**. If the Senator will pardon me, I was intending to speak to that point.

The **CHAIRMAN**. Be as brief as you can.

Senator **CASEY**. We have been over all this two or three times, and have become very familiar with it, and the practical question Senator Reagan suggests is what we wish to consider.

Mr. **GILBERT**. The practical method depends on the third method of getting the run-off. The second method, which I have just alluded to, is impracticable, because of the difficulties of understanding the conditions and putting together the various elements.

The third method is one of analogy. In the same general district we have the same general rain-fall at the same altitudes; that is, the general rain-fall varies with the altitude in the same district of country. If we have two drainage basins in the same district of country at about the same altitude, having the same character of surface as to declivities and as to soil, then the run-off from those two basins will be proportionate to their areas; and working on that principle, it is possible to determine the run-off by, in the first place, actually measuring the run-off from certain basins taken as types, and then measuring areas and declivities and examining soil conditions of any other areas of which we wish to know the run-off.

The soil conditions are usually similar through wide belts of country, or, more strictly, their variation is in sympathy with the variation of declivity. Surfaces of gentle slope are more receptive, and steep surfaces less, so that classification of catchment areas by declivities is also largely classification by soil conditions. The measurement of areas and declivities and the determination of the general altitude are the functions of the topographic survey. In my judgment the division of the work into (1) a hydrographic survey which shall determine by gauging the run-off of types of basins, and (2) a topographic survey, has the additional advantage that it indicates the reservoir sites which are to be considered; that it indicates the tracts of land which lie in such shape that they are susceptible of irrigation, and that it indicates the alternative routes for canals and the alternative sites for the head-works of canals to be used in conducting the water to the irrigable lands.

The **CHAIRMAN**. If an experienced engineer, having general information with regard to the storms that occasionally occur in a given section of country, were to proceed into a drainage basin, follow up the streams, and ascertain the places that are suitable for reservoirs, etc., after having, of course, taken into consideration the general area of the basin by observation, its declivities, etc., what would prevent him from locating those reservoirs and segregating the irrigable lands from the other lands, and doing all that work, with the maps that are already collected, without waiting for the topographic survey to precede him?

Mr. **GILBERT**. There is a class of streams——

The **CHAIRMAN**. Could that be done at all?

Mr. **GILBERT**. It could be done with reference to a certain class of streams, in which the catchment areas lie so high that the climate is unsuited to agriculture, so that the streams will have to be handled low down on their courses, of necessity, and where there are existing good maps; but even in that case the engineer would need to go over the ground, in order to satisfy himself that he has the best system of reservoirs—that the system he adopts will not some time have to be reformed. He will have to go over the entire field thoroughly to discover the available reservoir sites, in my judgment. Where there are maps in existence exhibiting the available reservoir sites that is not necessary; he can discover those that need to be considered from the maps; but in general existing maps do not serve that purpose.

The CHAIRMAN. Are the topographic maps sufficiently accurate to locate the reservoir and estimate the quantity of water the reservoir would contain?

Mr. GILBERT. The topographic map would give only a crude idea of the quantity of water the reservoir would contain, not a sufficient estimate for final comparison; but it would give an amply sufficient estimate of the area of the catchment basin, and through that, with the aid of such a gauging system as I have mentioned of the amount of water which would come to that point, it would give a preliminary estimate of the reservoir.

The CHAIRMAN. Would it not be sufficient for general purposes to have a general estimate of the catchment basin, with a gauging system carried on by the inhabitants, after the first instance? Would not that be sufficient for ascertaining the amount of water for practical purposes?

Mr. GILBERT. In my judgment, for practical purposes it is necessary to examine the country tributary to each site or storage basin under consideration in order to ascertain the run-off, and such examination is most economically made by a general work which covers the whole hydrography——

The CHAIRMAN. (Interposing.) Can not an engineer make that examination?

Mr. GILBERT. Yes, he can make that examination, but he can not make it as cheaply as the topographic survey can. A differentiation of functions comes in here. The work of the topographer and the work of the engineer are, to a certain extent, the same. They use the same instruments; they make maps, contour maps; but they work on different scales, and when a man who works with one scale, be it large or small, is diverted to do a piece of work on another scale, he works at a disadvantage.

The CHAIRMAN. Which is the larger scale, that of the engineer or that of the topographer?

Mr. GILBERT. The engineer's is the larger scale. The engineer, in order to make his estimate of cost, etc., needs to go into minutiæ.

Senator REAGAN. What is meant by a smaller scale?

Mr. GILBERT. A smaller map for the same area.

The CHAIRMAN. Then, as I understand you, the topographic work would have to be done over again in order to get sufficient data for practical work?

Mr. GILBERT. Yes, sir. On every site of an irrigation works—every site of a reservoir, every line of a canal—a special survey would have to be run. A topographic survey, upon its small scale, and made in the rapid manner that belongs to a small scale, will not afford the data for final estimates as to cost. It serves as a reconnaissance for all those purposes.

The CHAIRMAN. What use would an engineer, locating reservoirs and laying out ditch lines, make of the topographic survey if it had preceded him, leaving the hydrographic survey out of the question?

Mr. GILBERT. He would, in the first place, know with a fair degree of approximation the height above the stream of the land to be supplied with water and the point of the upper portion of the stream at which the water would necessarily have to be taken out in order to be carried to that land. He would be enabled to consider alternate points for diverting the water without running trial lines. He would know where to direct his final survey and how to determine his general course.

Senator MOODY. Mr. Gilbert, is a topographic survey an observation survey in advance of the definite and particular survey that is necessary in order to locate practically these works that are indicated?

Mr. **Gilbert**. Yes, sir.

Senator **Moody**. A topographic surveyor is ordinarily and usually an engineer, is he not?

Mr. **Gilbert**. The two classes of work are branches of the same profession, but in general the topographer has a different range of information.

Senator **Moody**. In organizing an effort to put a certain region of country under water, that is to establish a system of irrigation, would you organize two parties, one to go in advance of the other and make these observations, or would you organize one party, who would make the observations—a topographic map, or what is its equivalent—and then proceed after they had done that to make the detailed measurements and observations and all that is necessary to locate the reservoirs and carry the water to the lands?

Mr. **Gilbert**. I would organize two parties, and let one precede the other, even if their work could be carried on together. Even if one did not need the work of the other I would organize two parties. It has been found in the history of Western exploration and survey (changing gradually from exploration to survey) that it was necessary to have different lines of work separately performed. In the original Pacific Railroad explorations all kinds of observations and surveys were carried on together. The resources of the country did not permit cutting up into small parties, and it was necessary to travel in one body. The topographers, the engineers, the naturalists, all went together; it was all reconnaissance. Afterward, when the Hayden, the Powell, the King, the Wheeler surveys were organized, those methods were adhered to at the start, but were finally departed from. Eventually there was one party for triangulation, another for topography, another for geology, traveling in the same district, but traveling independently, because it was advantageous to have the movements of each controlled by the particular work to be done.

Senator **Moody**. Supposing you were starting out originally to open up a drainage district, what would be your plan? Would you not first make these observations that you speak of, and then follow them up with a survey or measurements and the requisite engineering work, just as you would in locating a railroad through the country?

Mr. **Gilbert**. Yes, sir.

Senator **Moody**. In other words, you would select the general plan by observation, by certain preliminary measurements, and then carry it out by detailed work. Would that be it?

Mr. **Gilbert**. Yes, sir.

The **Chairman**. Have you any further observations to make?

Mr. **Gilbert**. I have not.

The **Chairman**. Before you go I wish to inquire what your profession is.

Mr. **Gilbert**. I am a geologist.

The **Chairman**. Are you engaged in the Geological Survey?

Mr. **Gilbert**. I have been engaged in the explorations and surveys of the Government since 1871. I have been mainly occupied in geological work, but have done some geographical work and some surveying, and I spent one year in the study of irrigation problems in Utah.

The **Chairman**. What position do you occupy in the Geological Survey?

Mr. **Gilbert**. I am Chief Geologist. I have charge, under the Director, of the geological work.

Director POWELL. Mr. Chairman, I would like to have you ask Mr. ilbert the relative cost of doing the work of the irrigation survey ith the aid of the topographic survey and without it.

THE CHAIRMAN. Mr. Gilbert may answer that question.

Mr. GILBERT. Mr. Chairman, I have not given sufficient considera- ion to that matter to give a quantitative estimate of the cost. It is my ecided opinion that the cost would be much greater, several times greater, if the determination of the sites, etc., were made by trial lines and by reconnaissances of the engineers, instead of being made by a general topographic survey.

Senator MOODY. Will you state, as briefly as you can, the difference between what you call trial work, the running of trial lines and observations by the engineers, and the topographic work?

Mr. GILBERT. That is easiest illustrated by considering a railway survey. The railway engineers, wishing to go from one point to another, inquire of the people as to routes, if they have no personal knowledge of the country themselves, and in that way learn of several routes that may be compared. They follow out each one, making a line survey, similar to the survey that they would make for the location of the road for the purpose of seeing where the opportunities are. Having done that they then select one line as best, modify it perhaps, and make a final survey. Now, in a country where there has been a topographic survey they run no trial lines. Take, for instance, the Appalachian regions when the topographic work of the Survey is in progress. Where these topographic surveys have been made the railway engineers study the maps, and by such studying are able to compare the possible routes, and usually to eliminate from consideration all but one and go to that directly.

The CHAIRMAN. Is there not a difference between a railway survey, which passes through the country over the lowest elevations, and a survey for the purpose of conducting water, which is arbitrary and which must be run where the elevations will permit? Does the engineer surveying for the purpose of irrigation require those comparative trial lines? Must he not go into a valley and ascertain by his eye and by his level where water will run around the valley, and is not that the trial line that he has got to run? He has got to follow that line if he is going to cover the land below with water; he has got to follow lines that are easily found.

Mr. GILBERT. In simple cases, but not by the eye. He must do it by levels. The eye always deceives. A ditch always runs up hill, apparently. But where the problem is to consider whether several streams shall be handled together for purposes of irrigation, or whether a stream shall be taken out at some low point on its course or at some higher point, by a route that offers better facilities for construction, then a reconnaissance of some sort is necessary. If it is not made, then the most economical route may not be the one that happens to be found.

The CHAIRMAN. In that case would the topographic survey show the engineer the levels and the difficulties of construction with sufficient definiteness to relieve him from the obligation of examining the route personally? If he is going to make estimates, has he not got to go over the ground anyway?

Mr. GILBERT. It will eliminate all the possibilities, except one or two.

The CHAIRMAN. Would it be very difficult, after you had the point where the water could be diverted, to ascertain the possibilities as to where the ditch might be run? Could not that be determined by levels very readily, without much expense, and could not all the possibilities of the stream be determined by levels at a minimum expense?

Mr. **Gilbert.** Yes, sir; but the topographic survey is a determination with a very small expense indeed. While it figures up in the aggregate to some millions of dollars, its rate per unit is very small.

The **Chairman.** Is not a great proportion of the expense of the topographic survey for work in countries where you can not utilize the land for irrigation and where you can not utilize the waters for that purpose? Is there not a great deal of surveying outside of the particular basins that can be utilized for irrigation purposes?

Mr. **Gilbert.** As I understand it, the future irrigation of our arid region is going to be distributed over its whole extent. It is going to include districts where a few years ago the thought of irrigation did not occur, but where storm waters can be used; and the general survey is going to be one of the means of indicating those districts.

Senator **Moody.** So that the topographic survey will get the whole country ready for irrigation in the future.

Mr. **Gilbert.** Yes, sir.

Senator **Reagan.** So far as you go, does the topographic survey include the whole country or select districts?

Mr. **Gilbert.** As I understand the work it has been begun in various States and Territories in basins where there is immediate need for the determination of these irrigation questions. The selection of tracts for initial work has been made with reference to the earliest needs of the greatest number of people.

Senator **Reagan.** And that may be extended as necessity arises?

Mr. **Gilbert.** Yes, sir. But at the same time complete blocks of country have been surveyed; not small areas of a straggling nature, but the general plan has been to complete the whole area. The beginnings of the work, however, have been made where the present need was most urgent.

The **Chairman.** Does your topographic survey leave marks on the ground indicating altitude and other signs which can be followed by the engineer?

Mr. **Gilbert.** No, sir.

The **Chairman.** They leave nothing on the ground?

Mr. **Gilbert.** They give the indications of altitudes of points which can be found; of points that are otherwise fixed; for example, the junctions of streams, the crests of hills, etc.

Senator **Reagan.** When you get that initial point you take the map and it shows you?

Mr. **Gilbert.** Yes, sir.

The **Chairman.** If it was not at the point where you wished to locate your reservoir or your ditch it would be necessary to have an engineering survey from that point to ascertain the location of hydraulic works, would it not?

Mr. **Gilbert.** I do not understand you.

The **Chairman.** When you get a fixed point you have got to go from that with the engineering survey to ascertain the other point, have you not?

Mr. **Gilbert.** If we have indicated on a topographic map a piece of plain country, indicated by contours far apart, and beyond that we have a steep hill, indicated by the contours close together, then the contour which skirts the bottom of that hill is the contour indicating the upper portion of that plane surface, the portion to be commanded by the ditch, and that is something of practical value, even if there is no absolute point fixed. It is the edge of that plain. I do not know that I fully understand you.

The **CHAIRMAN.** To determine a definite point at which to locate your reservoir you will have to find a known point. The map will not show you.

Mr. **GILBERT.** The expression of the map is through contours.

The **CHAIRMAN.** I know the expression; but does it not require actual engineering to find other given points definitely?

Mr. **GILBERT.** Yes, sir.

The **CHAIRMAN.** After you have the initial point from your topographic survey, it requires engineering to determine other points?

Mr. **GILBERT.** The topographic survey gives the position and height of definite points with the degree of precision of the map, whatever that may be, and if you compare any two of these points by means of the contours you have their relative heights. Take the upper edge of a plain that may be irrigated. You have the height of that with reference to the stream at various places, and by tracing the proper contour line you have an approximate idea of the course of the lowest possible canal route.

The **CHAIRMAN.** By what instruments do you ascertain altitudes?

Mr. **GILBERT.** That is ascertained in different parts of the country by a variety of instruments. In the present work of the Survey it is obtained chiefly by angles of elevation and depression; but it is also ascertained for altitudes that are not very essential to the work of irrigation by means of barometers. It is also ascertained along the lines of principal streams, I understand, in the present topographic work, by spirit leveling, but the other gentlemen present are better qualified to explain that than I.

STATEMENT OF ALMON H. THOMPSON, IN CHARGE OF TOPOGRAPHICAL DIVISION OF U. S. IRRIGATION SURVEY.

The **CHAIRMAN.** Mr. Thompson, what is your profession?

Mr. **THOMPSON.** I am a geographer, in charge of the topography of the Irrigation Survey.

The **CHAIRMAN.** Will you state to the committee whether a topographic survey is necessary to an engineering survey for the purpose of irrigation, confining yourself in as short space as you can to that exact point?

Mr. **THOMPSON.** A topographic survey is the cheapest and most accurate way of obtaining the facts necessary to plan a system of irrigation works for any natural district or drainage basin, and the results can be given to the people in the shortest time by this method. There are three well-defined phases or steps taken in engineering work.

The **CHAIRMAN.** Those steps have been explained a good many times to the committee. State what use an engineer would make of a topographic survey in a given district?

Mr. **THOMPSON.** It is supposed by the topographers and most engineers that it will furnish him all the data necessary for a reconnaissance; that he obtains in that reconnaissance most of the data for his lines, which he then runs. It is not supposed that it will furnish him data sufficient to make estimates of construction, such as cuts and fills. It is supposed that he will have to do that particular step of the work afterward. But it is supposed that it will furnish him with all information necessary for the first two steps, with the exception of now and then a single trial line.

Senator **Casey**. Suppose the data had not all been ascertained, what course would he pursue to obtain that data; would it be the same course that the topographic survey had already pursued?

Mr. **Thompson**. Yes, sir; if he wished to obtain it over an extended area of country. If he wished to obtain it as the topography is obtained in a line survey, for a few feet on either side of the trial line he might run, he probably would not cover the whole country with his map.

Senator **Casey**. He would cover only that region that he had particularly under his eye.

Mr. **Thompson**. Yes, sir. But the practice of the best engineers of the present day seems to be to obtain the topography of the whole country, especially in regard to irrigation work; and in other countries——

The **Chairman** (interposing). In what other countries do the topographers precede the engineers?

Mr. **Thompson**. In India, and to a certain extent in California, in cases that have come under my observation, and in countries where new irrigation works are located.

The **Chairman**. Have you any reports from the Indian surveys where they insist on topography preceding the engineering surveys?

Mr. **Thompson**. No, sir; I have no reports, but such reports are in the library of the Survey.

The **Chairman**. You have no reports showing that?

Mr. **Thompson**. No, sir; nothing in my hands. But there have been topographic surveys conducted in India for a long time, and these surveys are made use of by the engineers in constructing new works. The engineers of that country, as in this, I believe, obtain maps to begin with.

The **Chairman**. In southern California you say the topographic surveys precede the engineering surveys for hydraulic purposes. In what instances?

Mr. **Thompson**. I was trying to think of the particular instance. A year ago I was in San Francisco and an engineer came to me to ask me about the topographic work, stating that he had been employed by some company in San Diego County to construct works for irrigation purposes, and that his first step was to make a contour map of the area with intervals of 10 feet.

Senator **Casey**. He made that in the particular region in which he was working?

Mr. **Thompson**. Yes, sir. I think he said the area of his map was about 10 square miles.

Senator **Casey**. Was it any more expensive for him to do that work for the purpose he had in hand than it would have been if it had been done by a preliminary survey by the State?

Mr. **Thompson**. In my judgment it was much more expensive than a survey on a general plan.

The **Chairman**. Would he not make it more accurate having in view the objects to be attained, and would he not direct the survey to the attainment of those objects?

Mr. **Thompson**. That is a hard question to answer. If, on the general survey a map was made having the same contour interval and detail, I think it would be quite as accurate as he would make it.

Senator **Reagan**. Would not the answer to that depend upon whether the survey was made with greater or less detail?

Mr. THOMPSON. Pardon me. I said if the map was made with the same contour intervals, which means with the same details.

The CHAIRMAN. Would not the engineer, in making such a contour survey as he deemed necessary, locate marks on the ground which he could use in his survey, and which would not be found in a general topographic survey?

Mr. THOMPSON. It is possible that he might make some special marks with reference to his construction work. Our surveys are all connected with the Land Office surveys. The Land Office corners are marked every half mile, and our surveys are connected with the Land Office work; so that the Land Office lines can be drawn upon our maps, and the connection between the topographic work and the Land Office work be determined.

The CHAIRMAN. Are the Land Office marks extended into the mountains where there is no market for the lands?

Mr. THOMPSON. My remark relates to areas where the Land Office survey extends.

The CHAIRMAN. They do not extend into the desert lands?

Mr. THOMPSON. They do survey large tracts that are desert lands. The State engineer of California, when he was planning a system of works for that State, made topographic maps with contour intervals of 10 and 20 feet and carried the work over a portion of the State, although he was not planning a reservoir system but only canal lines to use the waters running in the streams during the time of irrigation.

Senator MOODY. Have you charge of the work of the Topographic Survey as well as the Geological Survey?

Mr. THOMPSON. Only of the irrigation branch.

Senator MOODY. In what regions of country has the work been conducted under last year's appropriation?

Mr. THOMPSON. In the Arkansas Valley, in Colorado; in New Mexico, on the Mora and Gallinas Rivers, in the region of Santa Fé and Las Vegas; and on the Rio Grande, in the region of El Paso; in California, in the region about Lake Tahoe, on the head-waters of the American and Uba Rivers, and the northern branch of Stanislaus, and the head-waters of the Truckee and Carson Rivers; in Montana, on Yellowstone Lake and along the Yellowstone River, and in southern Idaho along the Boisé and Snake Rivers.

Senator REAGAN. And on Sun River?

Mr. THOMPSON. No, sir. My work did not extend to Sun River. That was done under the engineers.

Senator MOODY. What work has been done by the Topographic Survey in connection with the engineering work under this irrigation scheme and appropriation?

Mr. THOMPSON. Over the same areas?

Senator MOODY. Yes.

Mr. THOMPSON. The engineers were working in the Arkansas River drainage basin in Colorado and about Lake Tahoe, in Nevada and California.

Senator MOODY. Was that in connection with the topographic work?

Mr. THOMPSON. The topographic work was not immediately connected with the engineering work. The engineers were engaged, as I understand, in surveying reservoir sites.

Senator MOODY. Where was the engineering party under Captain Dutton?

Mr. THOMPSON. He had general charge of the whole engineering branch.

Senator MOODY. Whereabouts did the engineers follow and use the topographic work?

Mr. THOMPSON. In no case that I know of. The topographic work had not been finished.

Senator MOODY. All that the engineers did under last year's appropriation has been done independent of topographic work?

Mr. THOMPSON. Of our completed work, as I understand it. They have called on us for our field-notes in many instances.

Senator MOODY. Were you able to furnish them any field-notes of your topographic survey?

Mr. THOMPSON. I think none that were worked up so that we would be willing to say that they were reduced the best we could do. We have furnished them preliminary notes, always stating that fact. We have been engaged on office work in the reduction of our observations but a short time. Of course the field-notes given were in a crude state.

Senator MOODY. Then, so far as the work has progressed under last year's appropriation, the topographic work and the engineering work for irrigation purposes have been carried on separately?

Mr. THOMPSON. Yes, sir; distinct organizations.

Senator REAGAN. Do you mean to be understood that the engineers have not made any use of the topographic survey in the engineering and hydrographic work?

Mr. THOMPSON. Under this last appropriation?

Senator REAGAN. Yes, sir.

Mr. THOMPSON. I do not know of instances, except information that they have obtained from our field-notes, from questions they have asked and photographs of field-work that have been given them. The maps have not been completed.

Senator REAGAN. Have you furnished them any?

Mr. THOMPSON. Not yet, sir; because they are not constructed. We have not finished them.

The CHAIRMAN. The hour is up.

Director POWELL. Mr. Chairman, I would like to have five minutes' time. Neither of the gentlemen who have been speaking has seemed to fully comprehend what the committee desire, and I would like to have five minutes of your time.

The CHAIRMAN. There will be another meeting as soon as we can get the committee together, and you shall be heard.

Director POWELL. That is satisfactory.

The committee thereupon, at 12 o'clock m., adjourned, subject to the call of the chairman.

NINTH DAY'S SESSION.

WASHINGTON, D. C., *March* 22, 1890.

The committee met at 10.30 o'clock a. m.

Present: Mr. Stewart (chairman), Mr. Moody, Mr. Gorman, Mr. Reagan, and Mr. Jones.

STATEMENT OF WILLARD D. JOHNSON, TOPOGRAPHER, U. S. GEOLOGICAL SURVEY.

The CHAIRMAN. What is your profession or occupation, Mr. Johnson?

Mr. JOHNSON. I am a topographer. Under the general direction of Professor Thompson I have charge of the topographic work in the Division of the Arkansas River Basin—of the portion of that basin lying west of the Kansas line.

The CHAIRMAN. The present inquiry will be directed to the question of the connection between the topographic survey and the engineering survey for purposes of irrigation, and of whether and, if at all, to what extent, the engineering survey is dependent upon the topographic survey. Please confine yourself to that exact question. We have been over the general ground sufficiently.

Mr. JOHNSON. So far in the Arkansas Basin, there has been little connection between the topographic and the engineering surveys because the engineering survey has entered upon its work in this field in advance of the completion of work by the topographic survey. The outcome of a topographic survey is a map and every step toward that end has its place in a system. The data of field work, if considered separately, necessarily appear fragmentary and incomplete. The parts must be adjusted and co-ordinated by office work. In such work we are now engaged. The area surveyed was large—22,000 square miles, and the map sheets covering all of that area are now nearing completion. The topographic work began in the fall of 1888, and was carried uninterruptedly, with gradually increasing field force, through the following winter, the following spring and summer, and well into the succeeding winter—the winter just ended. Office work then began, five months ago, upon the whole mass of this material. Engineering surveying was entered upon early in the summer of 1889.

In this basin I had charge of the topographic survey only, under the direction of Professor Thompson; within the same limits there was also an engineer—a division engineer—in charge of the engineering survey, under the direction of Captain Dutton.

The CHAIRMAN. Who was the engineer in charge of that work?

Mr. JOHNSON. Mr. Bodfish. From beginning to close of his work I was in continuous receipt, from this division engineer, of requests for maps, for topographic maps, or for map data of any character. These calls upon me for map data were continuous, urgent, and annoyingly persistent—annoying for the reason that I have mentioned, that such data as I had must, until we should have fitted together the mutually dependent parts in office work, necessarily appear to others fragmentary, scarcely intelligible and misleading.

Mr. Bodfish understood this, yet insisted, very reasonably I think, that he nevertheless must have maps, that without them he could do little, and that little at a disadvantage. I was finally directed to furnish him with photographs of certain unadjusted pieces of map work. I regretted the necessity for this as I knew that he could not fully understand them, that only those to whom they were of the nature of memoranda could understand them, and finally adjust them. I wish to emphasize the fact that I was repeatedly urged to furnish the engineering surveyors with topographical map data as a guide in their special work.

The CHAIRMAN. Is Mr. Bodfish in town now?

Mr. JOHNSON. Yes, sir. This unfinished material, covering about 1,000 square miles on the plains of Colorado, the engineering surveyors, as I expected, could not interpret. Thereupon pending the final completion of the maps, they entered upon work in the mountains, where they had the benefit of the old Hayden survey maps, at least. To do this was comparatively easy, for in addition to the Hayden maps, this region afforded opportunities for several good sites, of which every one knew. In every great river basin, as well settled as that of the Arkansas, out of the great number of opportunities for storage and for conveyance of water, to be discovered only through systematic study of the grades of the ground over its entire surface, there naturally will be certain obviously good sites, or seemingly good sites, about which there will be general knowledge. To such spots Mr. Bodfish went and there ran his careful levels and made the accurate and necessarily expensive special surveys. Aside from such work as this he engaged in what Captain Dutton, in an earlier letter, of June the 10th, pressing me for maps, described as reconnaissance work. Captain Dutton said: "Mr. Bodfish's work during the present season can hardly be more than the reconnaissance work. Ultimately, of course, we must have the thoroughly completed map."

Over the mountainous area covered by the old Hayden survey we did revision work merely, adding only what would be necessary for republication on the larger scale proposed. Here, when my principal assistant, Mr. Bien, found himself carrying his general surveys over the region in which Mr. Bodfish was making precise local surveys, we were again met with calls for map data, and we again, of necessity, furnished the unadjusted data. This, though confessedly incomplete, was found a useful guide, and at other points in the same region similar data were afterwards furnished at intervals.

Mr. Bodfish was even here working at a disadvantage, and it was, and in my opinion, everywhere must be, only over such limited areas, where the problems are of simple character, that such work can be conducted with even limited success without that full knowledge of the entire area under examination, which only a topographic map can give—make it by what method you will, and call it by what name you will. Next summer, as Captain Dutton wrote me, they must have the thoroughly completed map, and by July they may have it—more than 20,000 square miles of it—an area nearly three times that of Massachusetts.

They have now, to be sure, the Land-Survey maps, but these maps do not show the topography, and even as horizontal plans, they are imperfect and misleading. It is the topography—the vertical departure from the ideal level surface, that is all-important. A map becomes topographical only when it shows this surface form; furthermore, it is now generally agreed that the most satisfactory method of representing topography is by means of contours, which have something of the graphic effect of shading, and at the same time convey information in regard to elevation and depression that is both definite and quantitative. It is a topographic map of this character that this survey is making.

The CHAIRMAN. The land-survey maps are of the plains regions?

Mr. JOHNSON. Yes, sir; and of the valley areas in the mountains also.

The CHAIRMAN. You had nothing to do with the topographic work of other divisions?

Mr. JOHNSON. No, sir. We did no work outside of the Arkansas River Basin. The rim of that basin on the north, west, and south, and eastward to the one hundredth meridian constituted the limits of our area. We have surveyed the greater portion of it, and much the more difficult portion. Within these limits I conducted the general survey, and within the same limits the engineers conducted here and there their special and unconnected surveys of high precision (by comparison with which the topographical work is approximate)—by widely different methods, at relatively great cost, and yet surveys merely, none the less. I deem it important to the general question, to which you ask me to confine myself, that it be understood that all of this work is of the nature of preliminary surveying. The several names for what are virtually one thing and directed to a common end are here, I think, more misleading than useful. In field work they serve in the division of labor. The expensive trial-line work is conducted with a special object directly in view. The general and comprehensive survey, which achieves a topographic map as its result, aims only indirectly to convey this special information. For whatever purpose it may be made, to whatever purpose it may be applied, such a survey accomplishes nothing more nor less than what I have described as a topographic map. Whether by an irrigation survey, or by a geological survey, or by a rail-road-lands survey, it answers to that definition—a map showing the form of the surface, as a rule by contours—and to each it is practically indispensable, as it directs attention, without waste of energy, to such special details as require minute investigation; and to each, as well, it affords a graphic base for the record of multitudinous additional facts in natural groupings.

The CHAIRMAN. Is it not possible for the engineers, in the mountains, to follow up the streams, and to make locations by observation, and with their instruments, without having the topography in advance?

Mr. JOHNSON. It is possible, especially in the mountains, and along the main stream lines; but even under such simple conditions the engineer may, here and there, fail to discover important facts. Expensive mistakes must inevitably, in my opinion, follow a course which appears, in view of the magnitude of the work contemplated, dangerously loose and unsystematic. And I am speaking of the trial-line method under favorable conditions. The best sites for storage will frequently lie to one side of the main streams, and to these the waters must be led; the great canals and the minor canals will run across the barren spaces between the main streams; and here also will be found the lands to be irrigated. Failure to carry examination over these interstream areas must occasionally result in wasteful work, and discreditable blunders. The topographic map shows all the possibilities and all the impossibilities.

The CHAIRMAN. Is there any difficulty in having an engineer pass along an ordinary stream and determine the possible and impossible sites with his instruments in a short time—in a few days, for instance?

Mr. JOHNSON. Yes, sir; to determine all the possible sites for a given stream basin; not simply the flat places along its immediate valley, but in the adjoining and higher valleys as well; to determine the lines—the best lines—of getting the water there, and away from there, on to lands in some less watered basin or unwatered table-land; to do these and other complex things, and at the same time to be sure that no fact has been overlooked, would, without a topographic map, or its more expensive equivalent, be more than difficult—it would, in my opinion, be impossible.

The CHAIRMAN. If you were going to locate a reservoir would it not be necessary to run trial lines for that particular place?

Mr. JOHNSON. After the topographic map had been made?

The CHAIRMAN. Yes.

Mr. JOHNSON. After the topographic map had been made it would still be necessary to resurvey, by relatively precise and expensive methods, all actual sites chosen for reservoirs and canals, or provisionally chosen with a small margin of doubt. These areas over which resurveys would of necessity be made would, however, appear in the great breadth of country represented by the map as spots merely. But the map is the indispensable and unerring guide to these spots. It says: Here spend your money; it will be wasted elsewhere.

The CHAIRMAN. The engineer has his levels with him, and can easily make experiments and make his locations without spending much time with trial lines?

Mr. JOHNSON. The area of country that a man can cover in that way, at a fairly reliable distance from his base, is exceedingly small, although it may appear to him large when on the ground. I find that, in criticising and examining in the field the work of my assistants, map in hand and merely by eye, the area thus revised by me is insignificant as compared with the body of land surveyed. The arid lands are of great extent. Such rapid work as the engineer may do by his general oversight, the topographer does also at wonderfully small expense, and much better and more rapidly, because his work is part of a system.

The CHAIRMAN. Suppose we take a river that has a great many tributaries. Each tributary, whether you have a topographic map or not, must be examined to see if you can store its waters, and the engineer follows up the tributary to its source. Would he not necessarily be guided to the localities where there will be flat places, where he can make reservoirs?

Mr. JOHNSON. He would not, with the map, need to do all this work in the first place; and without the aid of maps, he would not be sure to discover all the complex possibilities and impossibilities of the case to which I have called attention. He could not be sure without much more work than you refer to.

The CHAIRMAN. Take a mountain stream. Do they carry the water out on a table-land from the heights where they store it, or do they let it run down the channel, as a usual thing, to be taken out where it opens out in a valley?

Mr. JOHNSON. It is not so much a question where the water shall be taken out, as where it shall be stored. In many cases they might do as you describe; but my point is that years afterwards it might, in some cases, be found that great blunders had been made, involving the expenditure of vast sums, and that these blunders might have been avoided by the early expenditure of a very small, relatively insignificant, sum.

In the Arkansas Valley we began work in the vicinity of Pueblo. There irrigation work is actively carried on. Local engineers—men practically familiar with irrigation problems—had run trial lines all over that country. There had been much talk of taking the Arkansas out at some point far above Pueblo, to supply a large ditch and irrigate the country along its course by tap-lines, but it appeared impracticable to do so.

Many thousands of dollars had been spent, however, upon trial lines for various purposes over this same region, and had not discovered what our maps revealed immediately. My assistant, Mr. Hays, after working for a week or more in that region, said to one of the prominent engineers of Pueblo, "Why do you not take out a ditch at this place, and run it across here, and here, and store your water on the top of this tableland?" It had not appeared before that such a route was practicable. Appearances were against it. The gentle grades of that country are frequently misleading as to their dip. Mr. Hays urged, "Our maps demonstrate that it can be done." He showed the maps, rough preliminary drawings, but they gave, after an expenditure of a few hundred dollars only, what the local engineers had in vain spent thousands for. The Teller Ditch Company, so-called, was at once organized. A special survey, costing several thousand dollars, verified the prediction of the maps. This carefully surveyed line does not in detail coincide with that furnished by Mr. Hays, but it does coincide with fair approximation. It was enough that he had given them the general line. Construction work on this great ditch, to be the largest in Colorado, has already begun.

The CHAIRMAN. Do you mean to say it would have cost many thousands of dollars to have gone above, where it was suggested the water might be taken out, and to have run a random level to ascertain the practicability of doing so?

Mr. JOHNSON. No, sir; I do not. It would have cost very much less than the sum actually spent, and spent to no purpose. It would have cost less, because Captain Dutton's assistants would have gone about the work in a more systematic manner; but perhaps even they would not have thought of the line at all without the map to point it out. I claim for the topographic survey that we are doing it for the whole country. The engineer accomplishes the same result, but only here and there, and even then in a roundabout and expensive way. As we have the whole country to cover our methods belong to a unified system. I have here [indicating] a finished map showing the area covered by the preliminary sketch referred to. Here appears the ditch line as finally surveyed, practically coinciding with the line of the original, and demonstrating in this particular case the usefulness of such topographic data.

Senator GORMAN. Do I understand you to say that it is absolutely necessary, in your judgment, that this topographic survey shall be made before the engineers go upon the ground to determine this question?

Mr. JOHNSON. I am convinced, after a year of work among a people to whom irrigation questions are of vital importance, that it is in the highest degree economical, even essential, that the topographic survey precede the elaboration of plans for extensive and systematic storage irrigation. I am convinced that the topographic survey is the most economical means for ascertaining the necessary facts.

Senator GORMAN. How much more economical? Take the Arkansas basin. What would be your estimate of the additional cost of obtaining this information through the engineers without a topographic map?

Mr. JOHNSON. In my opinion it would be several times more expensive.

Senator GORMAN. Then it follows, in your judgment, in view of economy and results, that the special surveys should be suspended until after the completion of your topographic work.

Mr. JOHNSON. For the engineer to undertake his special examinations within a given area, in advance of the completion of the topographic map of that area, can only lead, it seems to me, to confusion and waste of money.

Senator JONES. Will you please explain your method of work?

Mr. JOHNSON. It has been so modified away from the prevailing methods of the text books as to be practically new. It is, in the main, that of triangulation—at first with the transit, by trigonometrical methods, but eventually, and chiefly, with the plane-table, by graphic methods. By this triangulation distances are determined indirectly, but more accurately than by direct measurement. Yet the work is initiated by a direct measurement—by the measurement of one line, the initial base line; and this initial base is measured with extraordinary care. One line, several miles in length, is thus determined, and from this line the triangulation scheme is expanded. The first triangle is obtained by measuring the angles from either end of the base to a third point previously marked. By means of the only known distance and the two known angles the two remaining sides of the triangle are found. This triangle is the unit of the system, hence the name triangulation. Such triangles are multiplied by computing additional sides, or distances between points, by measuring the angles only, and computing the distances. Such a system may be expanded over an area of 50,000 square miles perhaps, such as that of the Arkansas basin, and the final triangle with its computed distances may lie several hundred miles away from the initial base. The last computed distance it then becomes necessary to test by actual measurement, and the test of the last link is a test of the whole chain. This second measured line is called the verification base. I have indicated only the principles of procedure. The actual practice is somewhat more complex.

Upon the points located in this net of triangles the detailed map-work is based. The map is not made in one great sheet, but the total area is cut up into atlas-sheet areas, as in the case of the Arkansas basin, of about 1,000 square miles each. Speaking more accurately, the positions and boundaries of these atlas sheets are determined by the half-degree lines of latitude and longitude. Now, under the best conditions, upon each of these atlas-sheet areas, of nearly 1,000 square miles each, three of the precise locations of the primary triangulation should fall. The positions of these points must be furnished, to the map-maker proper, in terms of latitude and longitude, so that he can plot them accurately on his map sheet. This map sheet, mounted on a drawing board, and this again on a suitably constructed tripod, is then taken into the field and the map is made directly upon it, and upon similar, but smaller supplementary sheets. The drawing board, with its tripod of special construction, is called a plane table, and the method thereafter is, throughout, the plane-table method—a graphic method—the most direct and simple method for making a map, which is, itself, a graphic product.

The three points plotted upon the map sheet are termed its primary control. From these a secondary triangulation or control is spread directly upon the paper until many small triangles affording, perhaps, two hundred secondary locations, are determined within the area of the single primary triangle formed by the three primary points. This work is done by means of a telescope, with attachments similar to those of the transit, but mounted on a flat plate or broad ruler base, and resting directly upon the plane-table map sheet. Elevations are carried forward from point to point by means of vertical angles—a method of vertical triangulation.

So far, however, we have no visible map, merely control. The smaller, supplementary sheets, are now furnished to traverse men, as they are termed. The points of the secondary or graphic triangulation are plotted upon these traverse sheets, as the points of the trigonometric triangulation were plotted upon the larger sheet, and at these numerous control points the traverse men start and close. The elevation above sea-level of each of these points is also written on the smaller plane-table sheet, at a fine pricked hole, representing the located point. The method of the traverse man, as the name implies, is that of traverse, or meander—the same in principle with that of the trial line, but far less precise, and astonishingly rapid. The precision of detail, such precision as may be required, is attained by means of the check points. By the trial-line method, also a map may be made, but at relatively great cost, with great nicety in detail, but with gross inaccuracy in general proportion. These check points furnish with accuracy, and at a minimum of cost, that which line surveying, however carefully executed, can not furnish at all—the skeleton plan. By this method of triangulation a degree of closeness, in the determination of horizontal position and of elevation, may be reached, beyond the possibilities of the map to express, on the scale adopted. In estimating the cost of such topographical maps, per square mile, that of the primary control, though executed with great care, will be hardly more than 1 per cent., that of the secondary control perhaps 20 per cent. The traverse man, as stated, starts his line from a known point, and runs to other known points, checking and adjusting backward his error. The distribution of control points is, or should be, such that the probable error, after such adjustment, will be inappreciable or unimportant on the scale of the map.

In running his lines the traverse man depends for distances upon automatically counted revolutions of a wheel of his vehicle, and upon a further graphic triangulation, which he carries down even into this detail; for directions he depends upon his compass, and also upon this rough triangulation; and for elevations—for the detail of the grades of the surface, he depends upon the aneroid barometer. All of these approximate means are directly dependent upon the control locations, and errors are not cumulative. By running his lines close together and locating by intersection—by his rude triangulation, intermediate points, and by getting heights at such intermediate points by rude levels across between his lines, he surveys area and makes a map. I have here on this map, or large progress diagram, the area of an atlas sheet of 1,000 square miles, exhibiting the primary locations, the secondary locations, and the lines followed by the traverse men. You here [indicating] see the whole method graphically displayed. I have ruled this area into squares, representing square miles, on the scale of one inch on the map to one mile on the ground. It will be seen by following these red lines, which stand for the meandered lines, how well they are distributed for the control of area, as we say, and also the curious influence of the topographic configuration of the country upon this distribution. Within this area the traverse men have meandered, covering by their intersections belts of country on either side, a total distance of more than 3,000 miles. The total area must be covered by these belts and no blanks left. No blanks can be left, because, the method being a graphic one, a blank will appear as such on the map.

Senator MOODY. What has been the total cost of this topographic survey within the Arkansas basin?

Mr. JOHNSON. The total expenditure to date, for topography, in the Arkansas Basin, since I began work in the fall of 1888, has been $57,000. We surveyed 22,000 square miles, and, when completed, the maps will have cost $3 per square mile. This statement includes the heavy expenditure for equipment. I had about fifty animals, and seven or more separate camping parties. This expense for equipment, in this new field, will not have to be incurred again. Omitting this large item, the cost per square mile has been about $2.

Director **POWELL**. Let me add to Mr. Johnson's statement of topographic methods an explanation of the manner in which we get starting points for elevations. There is a plexus of railroads all over the United States. Lines now meander from the Atlantic to the Pacific coast, and from city to city of the interior, and these lines are connected at their termini, and they cross one another in various ways and at various places, forming altogether a net-work of roads. In their construction levels have been run, and by connecting their lines altogether we are able to discover discrepancies in these levels. The roads of the country have been very generous to us and have furnished us their profiles, so that we have in the Geological Survey nearly all the profiles of all the railroads in the United States. Whenever discrepancies between levels of the different roads are discovered we report them to the engineers of the roads, and the errors are soon detected. Having in this manner a vast system of level lines run all over the country, we have a basis from which the levels of the topographic survey can be reckoned.

Senator **JONES**. You select a height from which you desire to start a system of elevations, and then you run a level from the railroad to determine its elevation.

Director **POWELL**. Yes, sir; and check on other railroad levels from time to time.

Senator **MOODY**. Mr. Johnson, you are, I understand, the topographer for the Geological Survey?

Mr. **JOHNSON**. Not exactly; a topographer of the Geological Survey assigned to special duty on the Irrigation Survey for irrigation topography.

Senator **MOODY**. Is there any distinction between the expenditure for topography in the Geological Survey and for topography in the Irrigation Survey?

Mr. **JOHNSON**. I know little about that, sir.

Mr. **THOMPSON**. (Interposing.) The expenditures are kept entirely separate. Mr. Johnson's work was on the Irrigation Survey.

Senator **MOODY**. How do you keep the expenditures separate?

Mr. **THOMPSON**. The money allotted is drawn by requisitions on the Treasury, and the account kept separately.

Senator **MOODY**. How do you keep it separate?

Mr. **THOMPSON**. There was no geological work going on in that region.

Senator **MOODY**. Can you tell me where this topographic work was going on for purposes of irrigation?

Mr. **THOMPSON**. In Montana, Idaho, Colorado, California, Nevada, and New Mexico.

Senator **MOODY**. All for irrigation?

Mr. **THOMPSON**. Yes, sir.

Senator **MOODY**. In putting your work on topographic maps do you make any distinction between the irrigation topography and the general geological topography?

Mr. **THOMPSON**. In this case it was all for irrigation. There was no distinction, because it was all for one purpose, the Irrigation Survey. Had we been making it for geological purposes it would have been substantially the same.

Senator **MOODY**. What distinction do you make when you come to make maps? Do you have to go over the ground again for geological purposes?

Mr. THOMPSON. No, sir; the same topographical map answers for the geological survey.

Senator MOODY. Then the geological survey answers for the irrigation survey.

Mr. THOMPSON. Yes, sir. As the geological survey was previously conducted——

Senator MOODY (interposing). I mean as it is now in that country.

Mr. THOMPSON. I had charge of similar work of the geological survey before being assigned to this. The work was in principle precisely the same. It is simply an extension in methods of the geological survey topography.

Senator MOODY. That is, you add this specific detailed information as to elevations, etc., for irrigation purposes to your topographic surveys for geological purposes.

Senator JONES. Let me understand that. I understood Senator Moody to ask you, if, as a matter of fact, there is a geological survey for a given part of the country, this irrigation survey is made to supplement the geological survey.

Mr. THOMPSON. If the geological survey maps had been made in this region we would not have had to go over it again for the maps of the irrigation survey; but the geological maps had not been made.

Senator MOODY. Is it the intention to complete that whole country in one map eventually?

Mr. THOMPSON I can not speak as to what the intention is.

Senator MOODY. What I want to ascertain is this: Is it necessary, in your pursuit of geological information, for you to go over this ground again, after you have made this sort of topography?

Mr. THOMPSON. No, sir; not to make the map.

Senator MOODY. Now, can you put those divisions of the country together, where you have a map of one region on a scale of 1 inch to 4 miles and a map of another region, adjoining, on a scale of 1 inch to 2 miles?

Mr. THOMPSON. If we were to join these two maps, this map [indicating] would show the country more in detail. Every other one of the 100-feet curves represented on the large scale would exactly join with the 200-feet curves on the small scale, which covers 4 miles to the inch. They would join there. If the 4-mile map were photographed up so that it would be on a 2-mile scale, they would join.

Senator MOODY. Is it not sufficient, for engineering operations in irrigation, to take this geological survey map instead of making this irrigation topography?

Mr. THOMPSON. In my judgment, it would be sufficient.

Senator MOODY. You have this information, but you have to go on the ground and locate with more detail?

Mr. THOMPSON. Yes, sir. It is a mere matter of revision, quite rapidly done, because we take the map right into the field and draw the contour lines upon it.

Senator MOODY. Now, in your irrigation topography you do precisely the same thing in the first instance. That is the first work you do—what may be called the reconnoissance, the preliminary or observation work. You do precisely the same thing in both cases, for irrigation and geological topography.

Mr. THOMPSON. The same in method, but we obtain more refined determinations in relation to the streams.

Senator MOODY. It is important that we should understand what is essential in the way of appropriation for actual irrigation purposes and what is essential for geological purposes, that is, for the geological observation and survey that is going on, and what I want to know is whether we can use in this irrigation work the topographic maps that you have already made or are ready to make.

Senator JONES. As I understand, they are already made.

Director POWELL. This whole discussion is proceeding on a mistaken notion on the part of Professor Thompson of the import of your question. May I explain it?

The CHAIRMAN. Certainly.

Director POWELL. We have been doing work for a number of years, making topographic maps in the arid region. The ones that we have been making——

Senator MOODY. Did you make any topographic maps of this region where Professor Thompson had charge?

Director POWELL. No, sir; this is new work. I wish to speak of the relation of one to the other. A topographic map must be made for the geological survey and one for the irrigation survey, but they are one and the same, not two maps. The same map serves both purposes. There are certain areas of country where we need it on a scale of 4 miles to the inch; other regions on a scale of 2 miles to the inch. In the regions we have surveyed heretofore we have gone farther into the mountains. There we have made the maps on a smaller scale, but sufficient for our work in geology and irrigation alike.

Senator MOODY. What is the difference in paying the expense of this sort of topography out of your geological survey appropriation?

Director POWELL. None at all, if Congress makes a sufficient appropriation. It makes no difference.

Senator JONES. If Congress makes a specific appropriation for a geological survey the director would be obliged to expend it for that, and if there was a specific appropriation for an irrigation survey he would have to expend it for that, but he can make a map for both.

Director POWELL. The cost of the map necessary for irrigation over the cost of the map necessary for the geological survey is a trivial thing. It is involved in the running of the gradients of the streams.

Senator MOODY. We have secured for actual irrigation purposes $89,000 out of the $250,000, it seems, and the expense has gone toward this topographic work.

Director POWELL. What I am trying to get at is——

Senator JONES. I should think that objection would lie to the whole amount. The engineering and hydrographic work are no more important to the irrigation survey than the topography. They are all a means of finding out what is essential to the location of reservoirs and dams. It seems to me if you object to one, you must object to the other.

Senator GORMAN. Take this survey you have made. What would be the difference in the cost to the Government between using your topographic map for geological purposes and the one which includes irrigation as well as topography?

Director POWELL. One map serves both purposes.

Senator GORMAN. What is the difference in the relative cost of producing those two maps?

Director POWELL. That which is necessary to be done for irrigation purposes, over and above what is necessary for geological purposes, would not exceed 1 per cent.

Senator GORMAN. It would not be more than 1 per cent?

Director POWELL. No, sir.

Senator REAGAN. All that would be necessary would be to narrow the contour lines?

Director POWELL. No, sir; that is not necessary. The only additional work is the running of the gradients of the streams with accuracy.

Senator GORMAN. So that in this arid country you think it would be wise to make the appropriations to include both?

Director POWELL. Yes, sir. I do not think we ought to do the work twice. By my method when it is done for one purpose it is done for all.

Senator GORMAN. I would like to ask you, in view of what Mr. Johnson has said, why is it, in pursuing this inquiry, if the geological survey was absolutely necessary to economy and results, that you put the engineering parties into the field prior to the completion of the topographic work?

Director POWELL. I have explained that to the committee heretofore, but I will explain it again. Four or five weeks ago I explained to the committee that in the Arkansas Valley I knew of some reservoir sites, so that it was not necessary to have a topographic survey to discover what was already known. I knew that Twin Lakes was a reservoir site, and I knew of others. I had been studying that country for twenty-two years. I was at Twin Lakes twenty-two years ago.

Senator JONES. You had a topographic map of that country in your head.

Director POWELL. Yes, sir; I knew certain sites, and I said to my engineers, "We will not wait a year for a topographic map, but take the sites we now know, and examine them while the topographic corps is discovering the remainder." So I sent a small engineering party to make plans of those reservoirs, the sites of which were already known or supposed to be known.

Senator GORMAN. Is that the case with every engineering party that you sent out?

Director POWELL. Yes, sir. When we sent out an engineering party we knew much of the special ground it was going on.

Senator MOODY. Then for irrigation purposes you could have saved this $57,000.

Director POWELL. No, sir. Only a few sites were known and many had yet to be discovered; the topographic work had to be done to discover them and to find out how much water could be furnished by the several catchment areas, and to discover canal sites, dam sites, etc.

The CHAIRMAN. This engineering work for the purposes of irrigation only needs to proceed as the settlement of that region requires it. It does not need to be done in a day, because the land can not all be occupied in a day. As I understand you, the engineering party proceeds in advance of the topographers where reservoir sites are already known. Now, what is the difficulty in allowing the topographic survey to go on, and permitting the engineering to proceed independently of it? Must the engineering survey, particularly in localities where they want the water immediately, be retarded by waiting for the topographic survey, or may the engineers go on, using what topography you already have, and survey the known basins, make estimates, and let the people use them?

Director POWELL. Let me explain. There are two things that must be determined before the ultimate plans for construction of works can be approved and published to the people. We have got to know what water is to be controlled. If we make an error in that the whole thing is disastrous. If we plan a reservoir site and have not the data before us so as to know how much water has to be controlled for that reservoir site, the reservoir may be constructed, and the first great storm that comes along will destroy it, sweep it out. We must know what that drainage area is, what the supply of water is. That can not be determined by any other method than the one which I have adopted in less than ten to twenty years. I have done it by topographic methods in part. I have explained to the committee how I determined that. It is impossible to do it in any other way as quickly or as cheaply. Second, if we do not make a topographic map, we can not make reports until the end of a series of years after the streams have been gauged. Then, by taking the other method we make it cost five times as much, as I have already told the committee.

The CHAIRMAN. Do you mean to say that nothing can be done until the topography is complete in each?

Director POWELL. Let me illustrate. We can not put on the roof [illegible] a house until the walls are built. We can not erect the walls until the foundation is laid, but while we are laying the foundation we [illegible] haul the bricks and cut the shingles. For each particular basin or reservoir we must have the complete topography before we can report upon it. Suppose there is a little stream which will furnish 10,000 acre-feet of water in a year. I must know the drainage basin of that stream before I can plan that reservoir and know that there is 10,000 acre-feet of water to be controlled.

The CHAIRMAN. That is the work of your engineer, is it not?

Director POWELL. No, sir. No railroad manager would put the freight system, the passenger system, the ticket system all under one man. A house-builder does not employ the same man as a mason, a carpenter, and a plumber. My men are all engineers, but I have classified them, putting one class of work into one man's hands, and another class of work into another man's hands, so as to get the best work from each.

The CHAIRMAN. Then, I understand the work you have done in those localities where the topography has not preceded will be useless?

Director POWELL. No, sir. I shall have the topography ready for those districts before the plans are completed and the reports made. In two or three months the topography will be ready, and we can then tell what water the works will have to control by using the gauging of typical streams. The final report on the reservoirs of a stream can not be made until they have the topography. The engineers can not make their recommendations until they have. The work done in splitting the shingles for a roof is not lost, though it be done while the workmen are laying the foundations.

Senator GORMAN. Was the destruction of the dam in Arizona the other day caused by a disregard or lack of knowledge of these things?

Director POWELL. Yes, sir; the same as at Johnstown. They had miscalculated the amount of water they had to control, and when the storm came the dam would not hold the water.

The CHAIRMAN. Do you not think it was because there was not a sufficient waste-weir?

Director POWELL. My idea is that the dam at Johnstown was a good dam.

The CHAIRMAN. Had it a waste-weir?

Director POWELL. It had one but it was not large enough, for they had improperly computed the amount of water which had to be controlled.

The CHAIRMAN. Is it not easy to make an ample allowance

Director **POWELL**. Yes, sir; if you know what that ample allowance should be, but suppose you do not know.

The **CHAIRMAN**. In torrential streams it would seem to be best to leave as much waste-way as before the dam was constructed.

Director **POWELL**. There is something more on that point. There is no use of building a dam to control 50,000 acre-feet of water if the basin is not going to supply it. I want to know how much water is going to come down, and the way to get that hydrographic information is by using the topographic survey. There is no other way of doing that except at great expense. Every gentleman who has spoken on that point here has said it would cost from four to ten times as much to do it by other methods than that adopted by me. My own judgment is six times.

The **CHAIRMAN**. In gauging streams you gauge the actual amount of flow?

Director **POWELL**. Yes, sir.

The **CHAIRMAN**. You take the gauge of one stream and use that as a basis for other streams in the same locality?

Director **POWELL**. Yes, sir.

The **CHAIRMAN**. You do not use any topography in gauging streams?

Director **POWELL**. No, sir.

The **CHAIRMAN**. And the gauging of streams under any system would be expensive.

Director **POWELL**. If I want to know how much water will run off of twenty-five roofs, I find how much runs from one roof, and then multiply——

The **CHAIRMAN**. Your explanation of that was very good, and I appreciate the advantage of that method. Would not the experience of people living on a stream indicate——

Director **POWELL**. It is a very dangerous thing to depend upon the experience of people for the data necessary to plan engineering works. Ignorant guessing will not do.

The **CHAIRMAN**. You can not rely upon it; but you can see the marks from floods, and gain some information from the experience of the people who live on the stream. As I remarked yesterday, the storms in that country have had no parallel since 1861-'62, twenty-nine years ago.

Director **POWELL**. We are very fortunate in having a wet and a dry year together, and all over that country I have taken advantage of that, and have been gauging the typical streams. Something was said the other day by Professor Thompson about the maps made by other engineers in California and I have brought the maps of California with me.

Senator **GORMAN**. I would like to have, for my own information, a little more light on the question the topographer in charge of the Arkansas Basin brought up, as to the administration of office details. He states distinctly that in that case, where the engineers were put into the field to locate the reservoirs and so on, their work was retarded, and its expense greatly added to, because the topographic survey had not been made. Now I understand you to say that you had general knowledge of that particular locality. I would like to have further information about it, and I will ask you whether it is not an absolute necessity to stop the engineering surveys until the topographic map is made.

Director **POWELL**. The actual surveys of the reservoir sites themselves should follow the topography. Last year they could have done so, for I had topography in other districts; but they did not go into th districts in which I had topography already collected for a very potent reason.

Senator MOODY. What is that reason?

Director POWELL. I am proceeding to give it. The people of the Arkansas Valley were in conflict about water rights. It is a country that is densely settled, and they were suffering for water, and I thought it was wise to go and give speedy relief. So I went to the Arkansas Valley. The legislature of Nevada had made an appropriation to construct irrigation works, and they wanted to know where to put them, and I went there to solve the problem as soon as possible. So, in all the work I did, I went into densely populated districts, where the problem was pending over the people, believing the people were anxious for the information at once; and I attempted to get that information in the best way.

Senator GORMAN. Then it was the local pressure that made you pursue a course which was not economical?

Director POWELL. Yes, sir; not the solicitation of individuals, but the pressure that came from a knowledge of urgent wants of the people. But these urgent wants were represented by governors, by members of legislatures, by boards of trade, and leading men of the country. There are certain districts of country in the arid region already highly developed by settlement, and where the water supply of the smaller streams is already used during the season of irrigation. In these districts the people desire to know how to control the greater streams, and especially how to store the surplus water, which is very great, and I went into those districts where the problems were pressing for immediate solution. In those districts I already knew some of the facts, but not all, and I acted upon the basis of facts known. I knew certain reservoir basins, and I said, "We will go on and get the information about these basins and supplement our work by the topographic information which we are already collecting," for the topographic survey preceded the engineering survey by about seven months.

For a year or two past there has been excessive drought in the arid region and large areas of crops have perished by reason of them. In those districts the people wanted early information and I believed it was wise to give them that information and adjusted the work to the conditions existing. In entering upon the work I believed that some loss would be entailed, but that it would be entirely insignificant in comparison with the good that would be done. One of the places which I entered upon was the valley of the Rio Grande above El Paso, because the people in the valley had had their agriculture destroyed. The values involved amounted to millions, and I took up the problem to see what could be done to save those people, and have discovered a practical solution, and it has already been presented to this committee and to a committee of the House, and that conclusion has received the approval of both committees and they have introduced bills in both Houses to apply the remedy proposed. I might have proceeded by the other method to solve the problem in the same manner with a saving of $1,000 or $1,200, but a speedy solution of the problem seemed desirable and I shouldered the responsibility.

Senator GORMAN. Then, I understand that in the administration of this trust, if appropriations are made hereafter, you will complete the topographic maps before putting the engineers at work.

Director POWELL. Yes, sir. I shall have enough topography this year to employ my engineers for the next year.

Senator **JONES**. Has there been any waste of money in the location of such reservoirs as you have located?

Director **POWELL**. If we had had our topographic survey finished we would have had less lines to run and would have saved something thereby.

Senator **GORMAN**. What was the difference in the Arkansas Basin between the cost of making the survey in the way you made it and making it after you had the topography?

Director **POWELL**. It cost $1,500 or $2,000 more than it would have cost if done the other way.

Senator **GORMAN**. What was the total cost of the engineering party in that basin?

Director **POWELL**. I think about $19,500.

The **CHAIRMAN**. Has the work been completed?

Director **POWELL**. Only on certain reservoirs. The great body of the engineering has yet to be done, and the engineers will proceed with it with the maps in their hands, and do it right, and reach results that can be given to the people with confidence because all the facts will be discovered by the topographic survey.

The **CHAIRMAN**. I mean the topographic survey of the Arkansas Valley.

Director **POWELL**. It has been completed nearly to the one hundredth meridian.

Mr. **THOMPSON**. It is completed to 101.30.

The **CHAIRMAN**. What proportion of the Arkansas Valley has been completed?

Mr. **THOMPSON**. I am speaking hastily, but I should say that of the Arkansas Valley out to the State line, about four-fifths has been completed.

Director **POWELL**. Now, Mr. Chairman, you have seen that we are making topographic maps for the irrigation survey, and the reasons for making them have been given. It has also been explained that the same maps are to be used in the geological survey. The maps are made once, and only once, and serve both purposes. In other regions we are making the same kind of maps on the same scale for geologic purposes and the geological survey is going on in some regions where irrigation is necessary and the maps which are made for the geological survey serve both purposes. The irrigation-survey maps are all that is necessary for geology as well as irrigation; the geological-survey maps are all that is necessary for the geological survey and the irrigation survey. In another region of the plains we are making topographic maps for the geological survey, and I have brought them with me. You will see, as I spread them before you, that they are made on the same plan as the others and on the same scale, and in like manner reveal the storage basins. Here in Kansas is one of the finest storage basins we have ever discovered on the plains, and it has been discovered by the topographers of the geological survey. The topographic work had to be done for the geological survey, and in making these discoveries they added substantially nothing to the cost of the work. I wish, Mr. Chairman, to make it clear that the topographic survey is done but once, and then done for both purposes. I have explained this matter to the appropriations committee and you will find it in the report of that committee which I hold in my hand.

The **CHAIRMAN**. Was that map made previous to the irrigation survey?

Director **POWELL.** It was made last summer, at the same time that the irrigation topography was in progress in another region.

Senator **MOODY.** You are making maps by the irrigation survey which can be used in the Geological Survey?

Director **POWELL.** Yes, sir. All the maps made by the irrigation survey will serve for the Geological Survey, and all maps made for the Geological Survey will serve for the irrigation survey. [Refers to map.] You see here is the Arkansas River. Here is a little basin, 5 miles from the Arkansas River, at about the ninety-ninth meridian. This is in the subhumid region. We are pushing the topography for the Geological Survey in the subhumid region and pushing the irrigation survey in the region to the west.

Senator **MOODY.** [Indicating on map.] Is the water taken out there?

Director **POWELL.** Yes, sir; it is taken out there. We can create a lake there [points], and there is low land lying along there to which the water can be conducted.

The **CHAIRMAN.** Is there anything else you wish particularly to present?

Director **POWELL.** I have not yet had twenty minutes in which to make a clear statement of the case. If I could have twenty minutes I would like very much to have it. I have been so frequently interrupted that I have drifted everywhere.

Senator **MOODY.** Still you have given us much information, and it is always a good thing for us to suggest questions, because then you know what is running in our minds.

The **CHAIRMAN.** Could you condense what you have to say and send it in writing?

Director **POWELL.** I can.

The **CHAIRMAN.** Do that, and bring it in.

Director **POWELL.** I will attach it to my statement. If the committee want opinions about this matter I should like to have the Superintendent of the Coast Survey brought here. I want to say to you that I had selected the present Superintendent of the Coast Survey to take charge of this work. He had the matter under consideration when the President offered him the position he now occupies. He is one of the best hydrographers in America.

The **CHAIRMAN.** What is his name?

Director **POWELL.** Mendenhall. He is familiar with the problem, and has discussed it with me.

The **CHAIRMAN.** I think we will call him. I would like to hear what he has to say.

Director **POWELL.** If you will address him a letter, asking him whether my method, with which he is familiar, is the most economic, most thorough, and most speedy, I think he would answer.

Senator **MOODY.** Is there any necessity for topography for the surveys you make out on the plains?

Director **POWELL.** Whenever I am allowed I want to present to you the question of what kind of a survey is needed on the plains; it needs a slightly different survey from that of the mountain region.

Senator **MOODY.** Can you state, in a general way, whether there is any necessity for the topographic survey?

Director **POWELL.** Yes, sir; it is chiefly topography on the plains. Professor Thompson told you that the British Government has made a topographic survey in India. That government has covered much of India with a topographic survey, and I can bring you many volumes of the reports of that survey. Everywhere in the civilized world, with-ut any exception, they make topography the basis of an irrigation survey—in Italy, in Spain, in France, the French in Algeria, the Russians n their arid regions, and the British Government in India and the French and English engineers in Egypt, and I have specimens of the naps which they made with me if you wish to see them.

The CHAIRMAN. Suppose the engineers took the same instruments hat you use, what would be the difficulty of their making the topographic survey that would be necessary for their work in the same nanner that you make it preliminarily, but on a smaller scale, to ascertain where to locate their ditches, and all that?

Director POWELL. None at all if on the same scale; if on a smaller scale it would not serve the purpose. But I would not take the man who is to stand by the river gauging the water and break up his work by sending him away to discover reservoir sites or canal sites or the area and declivity of drainage basins. He has all the work that he can do on the rivers in measuring their flow. I would not take the man who is to plan the dam and have him measure a river 20 or 30 miles away, and hunt a canal site perhaps 20 or 30 miles away in another direction. I would divide the work among skilled men, so that each one should do his part in the most economic and thorough manner. All the men are engineers, all doing work of the irrigation survey, but the work is divided among them on the economic principle well known as the division of labor. On a railroad one man is not ticket agent, freight agent, engineer, brakeman, and surveyor, but the work is divided among the men, and each takes his proper part. So in the irrigation survey, the work is divided among the men and each takes his proper part, one to do topographic work, one to do hydrographic work, and one constructive work.

Mr. Chairman, you have already received statements from myself and my assistants of the amount of money allotted at the beginning of the season to the topographic work, the hydrographic work, and the engineering work, and you have learned that a sum of money was reserved for subsequent contingent expenses. That reserve fund has been chiefly used in two ways: the engineering and hydrographic work has been strengthened in some places, and a small amount has been used in that manner; but the principal part of the reserve fund has been used in making segregations of land as required by the statute. Everywhere throughout the country it has been found that the people were anxious that these segregations should be made at the earliest possible date.

The statute reserves them from the 2d of October, 1888, the date of the signing of the act, even though the selections are not made until some time later. Whenever they are made the date of reservation is the 2d of October, 1888, and there were two reasons why the people wanted these segregations made rapidly, first, that they might know what lands were withdrawn from occupation and sale under the desert land act, timber land act, and pre-emption act, and which could be settled only under the homestead act; second, they are exceedingly anxious that reservoir sites and canal sites should be withdrawn from sale that they might not fall into the hands of individuals for speculative purposes, and a great pressure was brought upon the Director of the Survey to make these segregations speedily, and the work was carried on with all the vigor possible. A great number of reservoir sites, such as mountain lakes, etc., already known, were re-examined through the aid of the Land Office plats and from the general geographic information in the possession of the Survey; and such sites were certified to the Land Office as being reserved under the provisions of the statute. The general information in the possession of the Survey also indicated that certain great tracts of land should be reserved under the statute. A reconnaissance of such lands has been made, the Land Office plats examined, and 30,000,000 acres of land have been selected for final examination in the Land Office, so as to exlude all lands on which legal filings have been made. In one case, on Bear River, in Idaho and Utah, the people were in conflict, and the governors and people petitioned the Secretary of the Interior asking that lands in that region should be protected from occupation at the earliest date as important reservoir and canal sites were being occupied, and the Secretary of the Interior, while I was in the field, telegraphed me a peremptory order to send officers to that region and make the necessary segregations, and it was done.

For more than twenty years I have been conducting explorations and surveys in the arid lands. During the first year of my work in that region my attention was directed to the arid land problem, and from that day to this it has been my chief study. My field of study has been threefold: First, I have studied the lands themselves and the waters which are to supply them, and the forest areas on which they are dependent. Then I have studied carefully the practice of irrigation in the United States, and much of it has grown up under my eye until 8,000,000 acres of land are now under canals in that region. Then I have provided myself with the literature relating to irrigation, especially the engineering literature. From all of these sources, and aided by counsel and advice from my assistants who are able men, I have gradually developed a system of survey of the arid lands. More than fifteen years ago I commenced the gauging of streams. More than fifteen years ago I commenced the selection of irrigable lands tentatively, and thousands of people—scores of thousands—have settled on lands selected by myself and under my advice, given through the agency of maps and reports.

The conclusions which I have reached are not hasty, for I have given to the subject the best thought and energy of my life. In the solution of these problems two men have been most intimately associated with me and they have been considering them to a greater or less extent for many years. I refer to Mr. Gilbert and Mr. Thompson. We have sometimes disagreed about practical methods, but ultimately we have arrived at substantially the same conclusions. And the plan which I have submitted to the committee and which I previously submitted to the Congress is the outcome of all that study. The theory was to make a practical survey at the smallest expense which would give the greatest amount of information to the Congress and to the people actually engaged in irrigation, and to do the work not in the interest of particular individuals or of corporations, but for all of the people; so that if the farmers were to control the waters for themselves they would know how to do it in a thoroughly economic manner, and if they were to engage corporations to do the work for them they would have the necessary information to make their contracts with intelligence.

I have witnessed the wasteful expenditure of much labor and money aggregating millions of dollars. I have witnessed the granting of rights to companies to furnish water that were improvident and I have witnessed the reaction from these unwise contracts expressed in conflict with the water companies and expressed in unfriendly legislation and local regulation by which improvident rights once granted were destroyed. It has been in view of all these facts that the establishment

water rights where they were improvident and wasteful, the growth
the vast system of conflict from water rights which now exist, the
pairment of the catchment areas of water by the destruction of
rests, and the many other problems which I have already presented
the committee, that the legal, industrial, and engineering problems
ve all been considered, and I have for years been gathering all these
cts and from time to time have been presenting them to the Congress.
nd the survey which I have gradually developed has been the chief
gency for the accumulation of facts for the people, and as finally organ-
ed, was intended to assemble them completely and thoroughly in
ch a manner as to be of the greatest utility to the farmers them-
lves and to be of the greatest value to the States and to the General
overnment in the regulation and establishment of rights under this
ew industry.

It has seemed to me that by far the most important thing to be done
the interest of the people was to make a topographic map on which
ould be assembled in a graphic manner the principal tracts to be con-
dered. I have, therefore, in the management of the early explora-
ons and surveys, and later in the conduct of the geological survey,
oroughly represented the purpose and importance of the topographic
ap, and the subject has been examined by a joint committee of the
wo Houses and met with its approval. It has also been considered
om time to time by the appropriation committees and moneys have
een granted for its construction. When a more speedy and special
urvey was demanded and the statutes required that the lands and sites
hould be segregated and the works planned and the cost thereof es-
imated, I stated that the basis of the work would be a topographic
ap; that the map which we were making in the geological survey
r its purposes would serve the purpose of the irrigation survey as
rdered by Congress, but that to wait for these maps much time would
e consumed; that as the work was then in progress it would take
bout thirty years to complete it, and that if it were desirable to prose-
ute the irrigation survey speedily it would be necessary to do the top-
graphic work for the irrigation survey, and that the maps then con-
tructed would serve the purposes of the geological survey; that topo-
raphic work must be done for each and both purposes, and if done for
ne would be done for both.

With this understanding the appropriations for the irrigation survey
vere made in terms requiring the preparation of the maps used—in the
ame terms that required the preparation of the map for the geological
urvey. The law, therefore, authorized the survey on the plan which I
ad recommended to the Congress and it has been faithfully pursued
according to that plan. I represented, before the appropriation was
made, that the map was necessary and the appropriation was made in
terms authorizing its preparation. The question now arises, Was that
plan wise? Is it the most accurate, the most economic, and will it give
results to the people in the shortest time? My views on this matter
have already been presented in part, but in a desultory manner from
the fact that they appear in interlocutory form and often complete answers were not possible. I therefore desire to make a summary statement of the necessity for a topographic survey as the basis of an irrigation survey.

Under the survey I have to discover diverting dam sites, reservoir sites, irrigable lands, and canal sites from streams to reservoirs and from reservoirs to lands. All these are called for in the act. Some method of discovery, then, must be adopted. To guess at them by riding over the country and then testing the guesses by trial lines is a very expensive method. It costs on an average $25 per mile to run a trial line on the ground. Altogether hundreds of thousands, perhaps more than a million of miles of trial lines would have to be run if this method were to be adopted, and the average expense of running a trial line, as shown by the experience of railroad companies in this country, is about $25 per mile. But I had already demonstrated that a cheaper method could be used. I had superintended the conduct of topographic surveys for several hundred thousand square miles and found that railroad engineers could use those topographic maps and save the expense of trial lines. They could take a topographic map and select a line and survey that one alone for construction purposes, and this is now the practice of railroad engineers everywhere throughout the country where our maps are made.

Let me illustrate the economy of this method by a single instance: The Canadian Pacific Railroad ran trial lines which cost $3,000,000, and then built the road along a route which was not the best, and then changed the route over part of its course; and it is now discovered that the best route was still not found. Had a topographic map of the country, 200 miles in width from the eastern terminus to the western terminus, been made it would have cost much less money and the best line would have been revealed and a great saving would have accrued, and the map thus constructed would have served the purpose of all the tributary lines within the district and the purposes of a geological survey and everything else for which topographic maps are needed.

I have stated to the committee, and have made the statement after a careful consideration and years of study of the special problem, that the trial-line system for the discovery of lands and sites would cost three times as much as a topographic map system and when completed it would be less satisfactory. But if the topographic system were adopted it would not only be cheaper and more satisfactory for the purpose, but it would also serve the purpose of the geological survey and all other purposes for which topographic maps are used.

But the use of the topographic survey does not end here. There is yet another use of the topographic branch of the work equally important with the one already given and which would require it to be done were there no other reason for it. I refer to its use in the hydrographic survey. The arid region is naturally divided into many thousand distinct drainage areas, each one of which must be considered separately in planning irrigation works, as each one is a catchment area for the water which is to be controlled and used in irrigation. That the waters in each basin must be measured in some manner is manifest for the following reasons: First, if works are to be planned the amount of water to be controlled by the works must be known in each case. The dams to divert water should not be too great, nor too small; if too great an unnecessary expense is incurred, if too small the entire catch may not be secured. For the planning of dams also it is necessary to determine the volume of the maximum flood. All this requires a knowledge of the mean annual volume, the minimum annual volume, and the maximum annual volume, and the maximum flood volume. Again, if canals are planned they should be neither too small nor too large; if too small they can not perform the service, if too great they are made too expensive. Again, the gradients of the canals must be determined, and this depends upon the amount of water which they are to carry. If the volume is small the gradient must be large, if the volume is large the gradient must be comparatively small. Then the reservoirs are to be planned.

For this it is necessary to determine the amount of water which can be stored. It would be unwise to plan reservoirs unnecessarily large for the service, or ~~so~~ small that they would not perform the service. How, then, shall these waters be measured? Now, experience and long observation make it manifest that the gauging with meters and nilometers of the waters of each of the many thousand districts could be done only at a great expense.

But a careful investigation of the subject had already revealed another method, and when its cost was computed it was believed by myself to be about one-sixth of the cost of direct gauging. This method has already been fully explained to the committee. It is proposed to use the facts gathered in the topographic survey necessary for the other purposes, and to gauge a few typical streams with great accuracy and to derive from these factors and the general rain-fall tables in differing latitudes, longitudes, and altitudes a system of formulæ by which the water supply can be computed for each district. Thus it is proposed to solve the problems in part by experimental demonstration and in part by computation. I believe that by this method hydrometric results can be obtained superior to the results by direct gauging, and it can be done for a very much smaller amount, making a saving equal to twice the cost of the topographic map. It is thus that the topographic method of doing the work as compared with the trial line and direct gauging method will cost only about one-fifth of the amount which those methods would cost. If, therefore, it is considered that it is the most accurate and the most economic method, it remains to be shown that it is the most expeditious. This will appear from a consideration of the following conditions: A number of typical streams are gauged, the maximum rain-fall of any special stream may not be found without taking the observations for a long series of years, but of a large number of streams widely distributed throughout the country. Maximum and minimum volumes will be repeated now here, now there, now elsewhere, from time to time. We thus are able to get this maximum and minimum in a few places in a comparatively short time, and by the use of the method which we have adopted of measuring catchment areas and their declivities we can easily determine the general extreme conditions in each case without waiting for the long period of time to elapse. It is thus clear that results can be obtained in a much shorter time by the method adopted. It was therefore believed to be more accurate, more economic, and more expeditious.

It must, then, be remembered that the topographic work must be done anyhow for the geologic survey. That question has already been examined at great length by Congress and approved, and the law directs it. Whatever is done for the irrigation survey is thereby saved for the geologic survey. But it seemed to Congress that the irrigation survey should be pushed forward more rapidly than the geologic survey, and therefore the expense of the map is charged to the irrigation survey and paid for out of the appropriations made for that work, except in those regions where the geologic survey is in progress: there the maps constructed are used for the irrigation survey.

There is yet one other question in this connection which has been raised in the committee and which deserves complete answer. It is this: Would it not be possible to do a little work in each district from year to year, just enough to meet temporary wants, but to supply those wants fully? Of the thousands of districts which I have mentioned, there is no one which is not already settled, there is no one which does not already require the information which this survey will give. It is not possible to do a part of the work in any one district and leave the whole unfinished and properly utilize that work. The entire district must be understood, surveyed, all the facts obtained, before any proper plan can be presented. Each such district must be completed before results can be reached which will be of value to the people and serve their needs. But more, it is sometimes the case that two, three, or more adjacent districts which lie in one great river system are interdependent; that is, they are so related that the problems in one can not be solved without at the same time solving the problems of the others. There will, therefore, be many cases where several districts, each having a distinct system of works, will have to be completed together. As the work of the whole arid region can not in all probability be done all at one time—because it can not be hoped that appropriations will be made for it in that manner, and if made it would be difficult to find the trained necessary officers and difficult to administer—there remains only the policy which has already been inaugurated, of selecting those districts where the problems are most pressing for immediate solution and of taking them in their order according to the best judgment of the officer who has charge of the work and administers the trust.

In conclusion, Mr. Chairman, I crave permission to earnestly urge the importance of doing this irrigation survey work in the most thorough manner. The extent of the area to be redeemed is involved in the question. If the work is well and properly done the greatest area can be brought under agriculture; if carelessly and badly done a much smaller area of agriculture will ultimately be developed. The relative cost of the construction of these works is also involved in good or bad work. If the work is badly done it may easily cost two or more times what it would if properly planned. This means ultimately differences of many hundreds of millions of dollars in all; and there is yet another consideration: All the waters of 1,500,000 square miles are to be used in irrigation; all the rain that falls from the heavens above those lands; all the waters that run in the brooks, creeks, and rivers. These waters are enormous, almost inconceivable powers, and they are to be controlled. It is possible to store these powers so that they will forever be a menace to the people whose agriculture will depend upon them. India, in which the waters have been stored for many centuries, is covered with breached reservoirs; and the problem of making these reservoirs safe for the people is considered the most important problem presented to the British engineers in India. That same problem is committed to the survey under my charge, and I think I have some realization of its magnitude. The officers associated with me in the work feel like responsibilities, and I must beg of you not to diminish that responsibility by prescribing methods of procedure in the work which must necessarily result in the preparation of plans with insufficient data, and in leading the people who construct the works astray, and submitting their property—their fields and homes—to imminent destruction and putting them in peril of their lives.

Mr. Chairman, for the long and patient hearing which you have given me I can only express most profound thanks.

NINTH DAY'S SESSION.

WASHINGTON, D. C., *March* 28, 1890.

The committee met at 10.30 o'clock a. m. Present, Mr. Stewart (chairman), Mr. Plumb, Mr. Moody, Mr. Jones, and Mr. Reagan.

STATEMENT OF SUMNER H. BODFISH, DIVISION CIVIL ENGINEER, U. S. IRRIGATION SURVEY.

The CHAIRMAN. What is your occupation, Mr. Bodfish?

Mr. BODFISH. I am an engineer in the Geological Survey, engaged in the irrigation division.

The CHAIRMAN. Were you engaged during last year in the irrigation work?

Mr. BODFISH. Yes, sir; I was engineer of the Arkansas division.

The CHAIRMAN. Will you state what use you were able to make of the topographic survey in the surveys which you made in the Arkansas division last year, and also state what necessity there was for such a survey in connection with your survey?

Mr. BODFISH. I have had no maps of the topographic survey in condition to use yet. The party has not yet finished its maps, as I understand.

The CHAIRMAN. Are topographic maps necessary for your engineering work in surveying for irrigation?

Mr. BODFISH. They are not absolutely necessary. If I had good topographic maps they would be very useful.

The CHAIRMAN. Can the engineering survey be carried on in advance of the topographic survey? In other words, can an engineering party do what topographic work is necessary for the purposes of irrigation?

Mr. BODFISH. I think it can. I think the topography should be under the immediate direction of the engineer, and such limited topography as——

The CHAIRMAN. What topographic work is necessary for irrigation purposes? Explain briefly how you carry on your engineering operations, to what extent you go into topography, and what use you make of it.

Mr. BODFISH. The irrigation problem, as I understand it, is simply stated: The first step is the discovery of a location for storage; second, the amount of water that you can store at that locality; third, the cost of storing that water, building reservoirs, etc., and fourth, the means of distributing the water over the country below and the cost of distributing it. In determining the location of a reservoir, if good topographic maps were in existence, they could be utilized, first, in a negative way, by keeping one from looking for a reservoir where there is great improbability of finding it; but as most of the reservoirs must be found on the streams and not off of them, it is better, in my opinion, for the engineer to search all streams, because unless a topographic map is made with great detail it is not possible to delineate everything in that map that might be utilized as a reservoir; this would be true, especially of a small one. The engineer himself should search every stream for the reservoirs, and having ascertained where they are, then make the necessary surveys for determining the amount of water that can be stored, and for estimating the cost of construction. Then he has to determine the amount of water that can be obtained there. If he knows the rain-fall, the topographic map would be of some assistance to him; but from the map alone it is impossible to positively determine the run-off; the true way to determine the run-off would be to measure it at the point where the reservoir is to be located.

The **CHAIRMAN.** Must you necessarily go into detailed measurements at all places you build reservoirs, in order to ascertain the run-off? Is it necessary to obtain the details with that degree of accuracy?

Mr. **BODFISH.** No, sir; because the necessities of the reservoir site would not require it. He can judge from the appearance of the stream at the time he is visiting it, by the high-water marks, or by talking with the inhabitants, or by comparison of the drainage areas above that reservoir site that he finds on maps, whether it is possible to build that reservoir. If it is a doubtful case, whether he shall build a great or small dam, it is a question he must make a careful examination to determine.

The **CHAIRMAN.** With regard to the construction of reservoirs on streams that are violent and torrential in flood times, what circumstances does the engineer take into consideration to determine what kind of a dam it is safe to build?

Mr. **BODFISH.** In almost all of those streams that are torrential there are high-water marks, because the torrential currents are so swift that they leave a mark; so he can determine whether it is a stream of that character.

The **CHAIRMAN.** Can he, from the declivities of the surrounding hills, without actual measurement, approximate the rapidity with which water will be forced against the dam in flood time?

Mr. **BODFISH.** I do not think he can.

The **CHAIRMAN.** He can not do that?

Mr. **BODFISH.** Not very accurately.

The **CHAIRMAN.** Then it is not ordinarily safe to build dams in these large torrential streams?

Mr. **BODFISH.** No, sir.

The **CHAIRMAN.** When you go into a stream like the Arkansas to build a dam high up, where it is torrential in flood time, how do you avoid the danger, and when you do build one, what precautions do you take?

Mr. **BODFISH.** If you do build one, the precaution would be to make it an overfall dam. The building of the dam would depend on the amount of water it would have to carry. If the stream is a rapid-falling stream, as is usually the case in those regions, the chances are very few of finding a good reservoir site; but you might find a gorge with a comparatively flat basin above, where you could store the water at a sufficiently low cost to warrant the construction of a high overfall dam.

The **CHAIRMAN.** Is it not sometimes possible to build dams in such places and turn the water over the rocks and give it as large a waterway as it originally had?

Mr. **BODFISH.** Sometimes; but I should say it is rarely possible.

The **CHAIRMAN.** In that country will not most of the dams necessarily be built out of the main stream?

Mr. **BODFISH.** In the Arkansas Valley?

The **CHAIRMAN.** Yes.

Mr. **BODFISH.** As far as I have become familiar with the Arkansas drainage basin, the reservoir sites are found on the streams.

The **CHAIRMAN.** Are there lakes on the streams which indicate reservoir sites?

Mr. **BODFISH.** Most of those I have found on the Upper Arkansas have been caused by glacial action. They have been caused by the terminal moraines across the original drainage lines. They have been natural basins in the past. Farther down the stream there are a few small ones that have been made by the washings-in from side gorges into the larger cañon, making banks between which you might build. Those are dangerous localities to build in, however; the foundations are precarious, and the large cañon, as a general rule, falls rapidly.

The CHAIRMAN. In utilizing these rivers, which class of reservoirs do you recommend the construction of first?

Mr. BODFISH. Those built on the streams.

The CHAIRMAN. They are much more expensive, are they not?

Mr. BODFISH. Well, that is to be determined. I have not seen the others yet.

The CHAIRMAN. You have not seen any except those which are on the streams?

Mr. BODFISH. No, sir; all I have found are on streams.

The CHAIRMAN. If you could find sites higher up, where the reservoirs could be constructed cheaply and safely, would it not be well to commence there and make your cheap reservoirs first?

Mr. BODFISH. I must say here, that the area that I have prospected over lies within the mountainous district.

The CHAIRMAN. I am speaking of the mountain district.

Mr. BODFISH. In the Arkansas Valley mountain district reservoir sites off the streams do not exist. It is a rapid-falling stream, and all of its tributaries are rapid-falling streams.

The CHAIRMAN. When you have surveyed and finished your work in the mountain regions, what surveys do you make for the purpose of ascertaining ditch lines, so as to show what lands will be under water when the works are constructed?

Mr. BODFISH. If the water is taken out of the streams directly below the mountain region, a trial line—what I would call a "fly" line—would be run from the point from which we wished to take the water out.

The CHAIRMAN. Would a topographic map be sufficiently accurate to enable you to dispense with that "fly" line or trial line?

Mr. BODFISH. If it was a good topographic map, well constructed, we might in some places dispense with the trial line.

Senator MOODY. You mean if it was a topographic map that was constructed under the supervision of an engineer, as an engineer would construct it?

Mr. BODFISH. Yes, sir.

Senator MOODY. It would have to be such a map, and not a mere topographic map—a map of the surface?

Mr. BODFISH. A general map of the surface may be good for general purposes, but not for specific purposes.

The CHAIRMAN. What proportion of the work on the Arkansas, for example, would be dispensed with if you had a good topographic map to begin with? How much cheaper would it be to make the irrigation survey if that preceded it?

Mr. BODFISH. I do not think it would be any cheaper, sir, in the Arkansas drainage basin.

The CHAIRMAN. You would have to do about the same amount of work at any event?

Mr. BODFISH. Yes, sir.

Senator REAGAN. If you had a topographic survey, would you have to make trial lines the same as you do without a topographic survey, in order to ascertain the extent and character of a drainage basin and to establish the lines for ditches?

Mr. **Bodfish**. No, sir; not necessarily.

Senator **Reagan**. If you would not, how do you make out that it would cost as much to make the irrigation survey with a topographic survey as without it?

Mr. **Bodfish**. As I understand it, a topographic survey means a survey of the whole district within the boundary lines of the drainage area.

Senator **Reagan**. That is what I mean, the drainage area and the country to be supplied with water and irrigated.

Mr. **Bodfish**. Even having a topographic map of the entire area, and even with the rain-fall given, I would not know the quantity of absorption or evaporation on the surface.

Senator **Reagan**. Would you know that by an engineering survey?

Mr. **Bodfish**. I could not determine the run-off of any stream.

Senator **Reagan**. You could not determine that in any way except by hydraulic experiments.

Mr. **Bodfish**. I could determine, by measuring the streams, the amount of water that runs off.

Senator **Reagan**. What I am trying to obtain from you is an explanation of the answer you made to the chairman, that it would not save any expense to have a topographic survey precede your irrigation survey.

Mr. **Bodfish**. If I had to do the same work after the topographic survey was made that I had to do before, it would cost more.

Senator **Reagan**. But would you have to do it?

Mr. **Bodfish**. Yes, sir. As I explained to you just now, I would have to weigh the amount of water that passes a certain point, any way, even if I had a topographic survey of the area.

Senator **Reagan**. If you had a topographic survey, would you not know the drainage basin from that?

Mr. **Bodfish**. Yes, sir.

Senator **Reagan**. Would you not know where you could fix your dam from that?

Mr. **Bodfish**. Not necessarily. It would depend upon how well the map was made. I mean by that, that a map showing 20-foot contours would not necessarily——

Senator **Reagan**. Would you not know the country that would be supplied by irrigation from a topographic map?

Mr. **Bodfish**. Not until I had located the reservoir. If I could not locate the reservoir from the map, I could not tell you what country I could cover.

Senator **Reagan**. How do you get the information as to where you shall locate the dam and reservoir?

Mr. **Bodfish**. By personal inspection on the ground.

Senator **Reagan**. And not a survey.

Mr. **Bodfish**. Yes, sir.

Senator **Jones**. I understood you to say a while ago that a topographic survey would save you from making examinations where it would be impossible to find reservoir sites.

Mr. **Bodfish**. It will in some cases, sir.

Senator **Jones**. Then there would be at least that shadow of difference between the cost of locating works with and without a topographic survey.

Mr. **Bodfish**. If the topographic map shows me the water flows over a drainage line that falls a hundred feet to the mile, it is very little use for me to go there to find a reservoir site.

Senator JONES. It would be no use to go there to look for a reservoir site?

Mr. BODFISH. No, sir.

Senator JONES. If you found that out from a topographic map, even if you could find it without the topographic map, then you would save something by the use of the topographic map?

Mr. BODFISH. Yes, sir.

Senator JONES. Then you do save something by the use of a topographic map in such a case as that?

Mr. BODFISH. I stated that ——

Senator JONES. I understood you to say that there would be no saving in having a topographic map.

Mr. BODFISH. I referred to the entire work of examination and construction and not to special cases. If I have a map of the entire area, and by examining that I can ascertain that there is one-fourth or three-fourths of that area that I need not consider, so much of my time is saved, and even if I had to examine all of those streams, I think personal inspection would cost less than a topographic survey of the whole drainage basin.

Senator REAGAN. If you should make a topograhpic survey on a stream, would you not know from that topographic survey where the narrowest gorge was?

Mr. BODFISH. Certainly.

Senator REAGAN. The facts as to the character of the soil, of course, you get by inspection?

Mr. BODFSH. Yes, sir.

Senator REAGAN. If you know the location of the narrowest gorge which will create the largest basin, is that not where you will locate your reservoir dam?

Mr. BODFISH. Not necessarily.

Senator REAGAN. What would be the exception to that?

Mr. BODFISH. The fall of the stream above, or other facts—whether it will hold a sufficient quantity of water——

Senator REAGAN. You do not take my whole question. I say after you have ascertained your basin by the survey is it necessary to go over that again, or do you suggest the idea of guessing at it?

Mr. BODFISH. I would not send an engineering party there to make a special survey of that reservoir site without having personally visited and examined it to see whether it was represented right on the map.

Senator JONES. If you were making an examination of a given watershed for reservoir sites, without a map of any sort or of any description, would you have to make a personal inspection of the entire territory?

Mr. BODFISH. Yes, sir.

Senator JONES. How would that be made?

Mr. BODFISH. First, by myself riding over the country, or by having some intelligent assistant, to whom I could delegate part of that work, do it for me.

Senator JONES. By simply examining it with the eye?

Mr. BODFISH. Yes, sir.

Senator JONES. Then, when you found the location, approximating, according to your judgment, the conditions required, what more particular examination would you have to make to ascertain the facts in the case?

Mr. BODFISH. I send one of my parties there to make the actual survey and ascertain what different heights of dam are required—how much water different heights of dam will contain.

Senator JONES. What does the party do?

Mr. BODFISH. They make a minute contour map, showing 10 feet of elevation, and they make a careful topographic survey of the immediate location of the dam.

Senator JONES. How would the topographic survey which you would have made by that party differ from the topographic survey as made now under the direction of the geological survey for the purposes of irrigation?

Mr. BODFISH. It is made in the same manner, but with a great deal more detail.

Senator REAGAN. More detail as to the actual place of the reservoir?

Mr. BODFISH. The contour of the basin is shown more in detail.

Senator JONES. The principal work would be at the particular place where you intended to locate the reservoir?

Mr. BODFISH. Yes, sir.

Senator JONES. And the examinations of the outlying ground would be less minute?

Mr. BODFISH. Yes, sir.

Senator JONES. Would those outlying examinations be more minute than the geological survey?

Mr. BODFISH. Yes, sir.

Senator JONES. And you would examine the whole drainage basin?

Mr. BODFISH. No, sir; the whole storage basin—the storage basin caused by the dam.

Senator JONES. You misunderstood my former question. I asked you in the beginning as to whether your examination of the storage basin would be more minute; then I asked you if your examination of the outlying region would be less minute.

Mr. BODFISH. That would not be examined at all.

Senator JONES. You would not examine anything except the area of the lake you intended to make?

Mr. BODFISH. No, sir; but if I could not ascertain from the land office survey the boundary lines of that drainage basin, I would meander it in a crude manner sufficiently to determine what the drainage area was; but I see no necessity of making a topographic survey over that entire area, showing the contour.

Senator JONES. It would make no difference whether that was steep or level, or slightly rolling or anything of that sort?

Mr. BODFISH. Nothing more than my eye would show.

Senator JONES. Then, as I understand you, your idea is that the topographic examination made in connection with the geological survey for irrigation purposes is entirely useless?

Mr. BODFISH. It is not absolutely necessary at all, sir.

Senator JONES. And in the location of the reservoirs, you think all that is necessary is to survey exactly and particularly the location of the lake and nothing else, except to get, in a rough sort of way, a general idea of the size of the drainage basin?

Mr. BODFISH. Yes, sir.

Senator JONES. Without regard to its topography?

Mr. BODFISH. Yes, sir. If I weigh the amount of water passing that point, I can weigh it more cheaply, I can measure its flow and quantity more cheaply there than I could make a survey of the reservoir basin, and then I would know the amount of water passing that point——

Senator JONES. Have you any definite idea what caused the destruction of the Hassayampa dam?

Mr. BODFISH. I have never seen the place, or any good maps of it, and I have no opinion as to the matter.

Senator REAGAN. In the construction of a dam is it a matter of any moment to know whether the drainage basin from which the water is to be collected is precipitous or level?

Mr. BODFISH. Yes, sir.

Senator REAGAN. Do you get that information by the eye or by a topographic survey?

Mr BODFISH. By the eye, sir.

The CHAIRMAN. Is there anything further?

Senator JONES. I would like to ask a question or two. In locating these reservoir sites as you indicate, after you get them located, you then, in selecting a route for ditches to take the water to the land, run trial lines to ascertain the relative elevations of the country, do you not?

Mr. BODFISH. I have to determine approximately the fall per mile that I can give that ditch when making the final survey.

Senator JONES. And would you not also have to find out where it ought to be located?

Mr. BODFISH. That would be part of the preliminary work, to discover that point.

Senator JONES. Would a topographic survey save any part of that expense?

Mr. BODFISH. That would depend upon the accuracy of that survey.

Senator JONES. Of course an inaccurate and worthless survey would not be of any value in any way or anywhere. I was asking with reference to the topographic survey made by the Geological Survey in this matter. The object of this inquiry is this: It has been stated here by certain gentlemen that that portion of the money appropriated by Congress for furthering this survey of the arid lands that has been used for a topographic survey has been wasted and thrown away, and that only that part has been valuable that has been put into the hands of the hydrographers and those doing engineering work as such. Now, what the committee want to know is the opinion of the gentlemen engaged in this work as to the relative cost of obtaining this information by the two different methods. Your way, as I understand you, is to secure the information by going onto the ground and making trial lines. Others think that a topographic map of the entire country facilitates matters. What we want to know is the relative importance of these different branches of the work, and my immediate purpose in asking the question I did was to find whether there would be a saving of cost to your work or the work you did if you had such a map as is being constructed in this matter, to indicate to you where you should locate your lines from the reservoirs to the lands to be irrigated, or whether it would be cheaper to ascertain that by making trial lines; that is, by making a survey yourself.

Mr. BODFISH. I should prefer to make the trial lines.

Senator JONES. That does not quite answer my question.

Mr. BODFISH. Even with the maps in existence I should rather make the trial lines for my own personal——

Senator JONES. I was asking about the relative cost. The point I intended to ask you was whether the topographic survey would enable you to make a correct and proper location of the ditch lines without making all these trial line surveys?

Mr. Bodfish. I understand the question, sir, and when I said i would depend upon the quality of the map I stated the whole matter.

Senator Jones. What is the quality of the maps——

Mr. Bodfish. I do not know the quality of the maps made in th Arkansas district. I have not had a chance to test them.

Senator Jones. You know the quality of the maps being made by th Geological Survey, do you not?

Mr. Bodfish. I know what kind of maps they make elsewhere, bu I do not know what they have made there.

Senator Reagan. This does not apply to any particular locality. I is a general proposition.

The Chairman. You say you know the quality of the maps made b the Geological Survey elsewhere than in your district. State what th is.

Mr. Bodfish. I know the quality of the maps made by the Surve in the East and I know the quality of some of the coarser maps of th West, but I do not know what they are doing on this irrigation surve work in making topographic maps.

Senator Jones. If you are not familiar with the maps, of course yo can not answer.

The Chairman. Have you examined any topographic survey maps East or West, that would be sufficiently accurate to be of practical us in locating ditches?

Mr. Bodfish. I do not think I have, sir.

The Chairman. Have you examined many?

Mr. Bodfish. I mapped, with my assistants, a fourth of the State o Massachusetts.

The Chairman. Made a topographic survey?

Mr. Bodfish. Yes, sir.

The Chairman. Then you have been engaged in that work?

Mr. Bodfish. Yes, sir; for ten years.

The Chairman. And were none of the maps constructed under you supervision or by you sufficiently accurate to select ditch lines by?

Mr. Bodfish. No, sir.

Senator Jones. Of what value are those maps?

Mr. Bodfish, They are of general value.

Senator Jones. Tell me something they can be used for.

Mr. Bodfish. You could locate a preliminary railroad line by one.

Senator Jones. Then why could you not locate a preliminary ditch-line by it?

Mr. Bodfish. Because a ditch-line is a rigid line. A railroad line i not a rigid line; it is covered by a variety of grades, steep and light A ditch line is comparatively a rigid line and can not be determined b anything but the lightest grades.

Senator Jones. Do you not run a preliminary line for a ditch lik you do for a railroad and then make the permanent location of th ditch?

Mr. Bodfish. No, sir.

Senator Jones. You make the permanent location at once?

Mr. Bodfish. We make an approximate location by running a comparatively rigid line first.

Senator Jones. So that no secondary work is necessary.

Mr. Bodfish. Except for cross-sections and cost of constructio For instance, if I am to run a preliminary line as I did in Kansas starting from near the Kansas and Colorado line, I ran a preliminar line to see where ditches could be run to take water from the Arkansa

River just west of the Colorado and Kansas line. A grade of about a foot and a half to the mile was determined upon before the line was run and a line leveled out and meandered out on that grade to see where it would go, how soon it would get on top of the bluffs, and where it would pass through those bluffs—whether through bad or good cuttings—and the deviation on the grade from one foot and a half was very little.

Senator **JONES**. If you had a similar survey to that you made in Massachusetts for that particular section of country you went over could you have determined with approximate certainty whether or not that ditch was feasible, without making your survey?

Mr. **BODFISH**. I should not have assumed to use my Massachusetts work for that purpose without running a random line over the ground.

Senator **JONES**. Then if there had been just such a survey of that country as you had made in Massachusetts, it would have been of no practical use or value in determining whether or not that ditch line was feasible?

Mr. **BODFISH**. No, sir; it would not have been of much value.

Senator **MOODY**. In your surveys in the Arkansas River district did you make use of any topography that had been executed in that district?

Mr. **BODFISH**. No, sir.

Senator **MOODY**. Then whatever work the engineer corps has done with reference to irrigation has been done entirely independently of any topography?

Mr. **BODFISH**. It has in the Arkansas division.

Senator **MOODY**. Do you know of any other division where topography has been used?

Mr. **BODFISH**. I do not know anything about what has been done in the other divisions, sir.

Senator **MOODY**. Of course I understand that you want to answer accurately; your mind runs in that direction; but do you know, in a general way, of any use that has been made of the topography that has been going on under the geological appropriation or under the irrigation appropriation?

Mr. **BODFISH**. I do not know of any use that has been made of it.

STATEMENT OF GEORGE E. CURTIS, METEOROLOGIST AND HYDROGRAPHER U. S. IRRIGATION SURVEY.

The **CHAIRMAN**. Mr. Curtis, what is your occupation?

Mr. **CURTIS**. Meteorologist and hydrographer.

The **CHAIRMAN**. Where have you been engaged in that occupation?

Mr. **CURTIS**. In the Geological Survey.

The **CHAIRMAN**. How long?

Mr. **CURTIS**. In the office since last June; in the field since the preceding December.

The **CHAIRMAN**. What section of the country were you in?

Mr. **CURTIS**. Colorado and New Mexico.

The **CHAIRMAN**. What are the duties of a hydrographer?

Mr. **CURTIS**. The duties of a hydrographer are mainly to measure the discharge of steams.

The **CHAIRMAN**. What particular duties did you perform? Were you measuring the streams?

Mr. **CURTIS**. While I was in the field my duties were in connection with a camp of instruction for hydrographers, and after having finished those duties I returned to the office.

The CHAIRMAN. What is a camp of instruction?

Mr. CURTIS. It is for the instruction of young hydrographers who are about to take the field in different parts of the West. My duties were to give instruction in meteorological and hydrographic observations.

The CHAIRMAN. Explain, in brief, how you ascertain the flow or discharge of water in a stream at a particular point.

Mr. CURTIS. A cross-section is selected at which the river has a uniform slope, and which is a region both of minimum deposition and of minimum corrasion. Soundings are made, and the cross-section is divided into partial sections whose area is computed. The average velocity of the current is then measured with the current meter in each partial section. From its known area, and from the average velocity of the current, the discharge through each partial section is computed, and the sum of the partial discharges is the total discharge of the stream.

The CHAIRMAN. Can you tell from what the velocity is when the water is low what it will be when the water is high?

Mr. CURTIS. No accurate determination can be made except by actual measurement.

The CHAIRMAN. The velocity of the water is influenced by the water coming into contact with the land, either on the sides or on the bottom of the stream?

Mr. CURTIS. The friction and the slope.

The CHAIRMAN. When the river is high the middle of the stream has less friction than the sides and bottom. How can you estimate for that?

Mr. CURTIS. The velocity is determined in different sections of the stream at every gauging, and gaugings are made at as many different stages of the stream as possible.

Senator JONES. How do you determine that? By actual measurement?

Mr. CURTIS. By actual measurement with the current meter.

The CHAIRMAN. Then you must examine the stream at flood times?

Mr. CURTIS. Yes, sir; at all heights.

The CHAIRMAN. That would take a great many years?

Mr. CURTIS. No, sir; in a usual year the——

The CHAIRMAN. There have been several great floods on the Pacific Coast. There was one in 1849, another in 1861, and one this year—a great flood, overshadowing the others. How do you ascertain the facts for such years?

Mr. CURTIS. Those are unusual cases.

The CHAIRMAN. But they must be obtained.

Mr. CURTIS. If not measured, the discharge at such times can only be estimated, but frequently estimated with considerable precision.

Senator JONES. Do you find that the same amount of water is discharged at the same flood-height at all times? For instance, if you have a gauge in a river, would the discharge at the 20-foot mark be the same at all stages?

Mr. CURTIS. Not necessarily; in fact, in some large rivers, as for example the Mississippi, it has been found that the discharge is different in rising from what it is in falling water.

Senator JONES. Is there a difference at different periods of a rise as to the amount of discharge at a given point?

Mr. CURTIS. If I understand you, those are fine questions that are of little economic value; they are principally of scientific interest or important in connection with river hydraulics.

The CHAIRMAN. What use do you make of the topographic maps in hydrography?

Mr. Curtis. None, in the actual conduct of the work.

The Chairman. You rely upon your measurements of the streams?

Mr. Curtis. Entirely.

The Chairman. Are you a practical engineer?

Mr. Curtis. No, sir.

The Chairman. You are simply a hydrographer?

Mr. Curtis. Yes, sir; and meteorologist.

URTHER STATEMENT OF EDWIN S. NETTLETON, SUPERVISING CIVIL ENGINEER ROCKY MOUNTAIN REGION, U. S. IRRIGATION SURVEY.

The Chairman. I believe you have already given your opinion that t is not necessary that a topographic survey should precede the engineering survey for irrigation.

Mr. Nettleton. I have.

The Chairman. How much use could you make of an ordinary topographic survey in the engineering work?

Mr. Nettleton. To an engineer entirely unacquainted with the country a good map would be somewhat of a guide to study in his office before entering the field, but after that I do not think it would be of much or any value to him; that is any topographic map that I have seen made in this country.

The Chairman. Have you examined the topographic maps that have been made by the Geological Survey?

Mr. Nettleton. Yes, sir.

The Chairman. Pretty extensively?

Mr. Nettleton. Yes, sir. I have lately looked over pretty nearly all of the maps, including all the western ones that are published.

The Chairman. When they make a topographic survey of a section and then of another adjoining section, how do they join their work together?

Mr. Nettleton. I am not familiar with the way only from what I have been told and from some work I have seen in the office. The work of making these surveys is done by a great many different small parties who are sent out into the field. Their work is sent into the office in sheets, covering small areas, and the sheets are adjusted one to another; and it has been found in practice, I think, that different topographers will not complete the contours on their sheets so they will join. Many times there are considerable errors, and those have to be adjusted in the office.

The Chairman. They average them?

Mr. Nettleton. Yes, sir.

The Chairman. Bring the lines together?

Mr. Nettleton. They are made to represent a picture with a reasonable degree of accuracy.

The Chairman. That is done for the purpose of learning the general geography and topography of the country?

Mr. Nettleton. Yes, sir.

The Chairman. Made up in that way, as I understand you, they would not be of any practical use in the accurate survey needed for irrigation?

Mr. Nettleton. I consider the work of locating and surveying reservoirs and establishing lines of canals as being work that requires greater refinement than it is possible to secure with a topographic survey like we are doing or can afford to do. For instance, in the mountains the contour lines are supposed to be 50 feet, vertically, apart. In computing a gradient of less than 50 feet in a mountain country, in order to establish reservoirs or ditch lines, it is necessary to make observations and computations of which no note can possibly be taken from a topographic map. Contour lines 50 feet apart might omit to show a proper reservoir site, because the reservoir site might be only 40 feet high.

Senator **REAGAN**. You mean 40 feet of altitude?

Mr. **NETTLETON**. Yes, sir; vertical height.

The **CHAIRMAN**. That is the scale, I believe, on which they are making their topographic maps in the mountains?

Mr. **NETTLETON**. Yes, sir; 50 feet.

Senator **REAGAN**. Do you know what scale is employed generally by the topographic survey on the lower lands?

Mr. **NETTLETON**. I think 20 feet is the smallest scale they are working on, but I am not certain about that. I think the scale is 20 feet on the plains and 50 and 100 feet in the mountains. I am not positive as to the exact scales.

Senator **REAGAN**. If the maps were made on a scale of 10 or 12 feet, would that make a difference, in your opinion?

Mr. **NETTLETON**. I do not think that even would be sufficient.

Mr. **REAGAN**. I am not talking about the details.

Mr. **NETTLETON**. It would be of greater assistance. Ten or 12 feet contours in the mountains would show the possible existence of a great many more reservoir sites than 50-feet lines would.

The **CHAIRMAN**. But after knowing the possible existence of sites, what would be necessary to know actually what could be done in each particular case?

Mr. **NETTLETON**. To make what we call the engineering survey, or a topographic survey sufficient in detail to determine the area and holding capacity of that reservoir.

The **CHAIRMAN**. Do you invariably visit and inspect the ground before you make any survey?

Mr. **NETTLETON**. Yes, sir. In regard to reservoir sites in the mountains, a practiced engineer can generally determine with his eye, without the aid of instruments, what is a possible reservoir site and what is not; but generally the engineer looking for reservoir sites or making preliminary examination has a hand-level. He can get onto a suitable point and tell very nearly with his hand-level where the water line will be; and standing on one side of a dam site he can trace pretty near the water line. If that shows an area sufficient, and the dam can be made without too great expense, then he orders a survey. That survey is made accurately enough to determine quantities in the dam, the cost of making the dam, and also the holding capacity of the reservoir.

The **CHAIRMAN**. Where you construct reservoirs sufficiently strong to withstand floods, what elements or facts must be taken into consideration?

Mr. **NETTLETON**. There are two ways of providing against floods. One is by an overfall dam, which must, of course, be made very secure on its back side and on its foundation. Another is, where the floods are not very torrential and where the discharge of the stream can be provided for by making a waste-way lower than the crest of the dam, leading off to one side or one end of the dam.

The **CHAIRMAN**. Where you use a waste-way the question will be in getting it large enough for all possible contingencies?

Mr. Nettleton. Yes, sir. The experience of the last year or so eads me to believe that that matter has not had sufficient study; that ve have not paid sufficient attention to the occurrence of heavy storms ind sudden floods; but the destruction of the two dams that have reently occurred ought not to be used as an argument against constructng reservoirs.

The Chairman. Why not? That is a question that concerns the ublic very seriously.

Mr. Nettleton. In the case of the Johnstown disaster, the waste-ray was evidently large enough to carry off the flood that caused the lestruction of that dam; but that was an unprecedented storm—seven nches of rain fell within a few hours on that drainage area. The reservoir was used for fishing purposes, and in the waste-way a grating f iron rods an inch in diameter, set very close together, had been put n to keep the fish from running down the stream. This tremendous torm brought down leaves and brush, and one large log, which lodged gainst this grating. The man in charge, or the only man who was here having any authority, was a young engineer, who, instead of lowing out the waste-way with dynamite or some other explosive, comnenced to raise the embankment of the dam, which had settled and ras low in the middle. He commenced putting loose earth on the top, nd the water raised faster than he could raise the dam; at the same ime the outlet was partially choked up with this rubbish. It is my pinion that if that grating had been taken out and the waste-way kept lear there would have been no disaster.

The Chairman. Then, in ordinary dams you would not have those ish-traps?

Mr. Nettleton. No, sir. I would do just the opposite. There are laces in the old country where they put the waste-way very considerbly below the crest of the dam. Then if they want to utilize nearly he whole capacity of the dam, they put up posts and some kind of temorary wicker work of straw, that will hold the water until it gets to a ertain height. When it gets to that height it will break away—go out efore the water rises to the top of the dam, and that leaves a very large pening for the protection of the dam——

The Chairman. Have you any knowledge of this other disaster rhich occurred in Arizona?

Mr. Nettleton. Nothing except what reports I have seen in the ewspapers. But that was evidently caused by an insufficient waste-ray, causing the water running over the top of a loose-rock dam.

The Chairman. It was constructed for an overflow dam?

Mr. Nettleton. No, sir; it was not so designed——

The Chairman. And the waste-way was not sufficient to let the water o by?

Mr. Nettleton. No, sir.

The Chairman. Do you not think that is one of the things you have ot to examine with great care?

Mr. Nettleton. Yes, sir. I think one of the most important things n locating dams in running streams is in the first place to get the hisory of the stream, and if you can not get information in relation to the reatest floods that have occurred, observe the highest water-marks hat can be found.

The Chairman. Mere gauging will not give you that information?

Mr. Nettleton. No, sir, except in an exceptionally high stage of he water. I would provide for the greatest discharge ever known on he stream, and that to make it safe, I would double that capacity, in case there was a great deal of property or many lives depending on th breaking of the dam. Such things do not cost very much.

The Chairman. You can in no stream make the waste-way sufficientl large to take a flood through.

Mr. Nettleton. A waste-way is not always the best way to get ri of floods. Sometimes the best way is to take the water over the cres in whole or in part.

The Chairman. The overflow dams are very expensive, are they not

Mr. Nettleton. If you have solid rock for the foundation of you dam, and rock for the overflow water to strike on, a masonry dam is no very expensive.

The Chairman. Are there not some streams in the West where an dams, even masonry dams, would be unsafe; for instance, those stream where they have landslides in consequence of cloudbursts, which brin down immense bowlders?

Mr. Nettleton. There are places in the mountains where I think i is unwise to try to dam those torrential streams. In the first place, the dams are of no use after you get them, filling up with sand and debri and making an over-fall dam without any holding capacity.

The Chairman. Do those mountain streams carry evidences on the ground that such floods have occurred, as a usual thing?

Mr. Nettleton. Yes, sir. An engineer can generally find high-water marks.

The Chairman. And large bowlders which have come down the stream?

Mr. Nettleton. Yes, sir. Especially where there is timber growing, you will frequently find the trees scarred and flood-wood lodged in the crotches of the trees, high above where one would suppose water ever could have reached, but yet it is there.

Senator Moody. You are acquainted with these topographic maps that have been made by the Geological Survey?

Mr. Nettleton. Yes, sir; I have seen them.

Senator Moody. What use can be made of those in the Land Office in fixing the boundaries and the area of the reserved lands provided for?

Mr. Nettleton. These topographic maps show only the topography of the country, without any reference to or connection with the Land Office surveys; and they give no information as to the character of the soil, whether or not it is a timber or rock covered country or irrigable and agricultural lands. They just simply show its slopes, and what the character of its slopes are. While a topographic map might show a fairly good looking country, still the land might not be worth segregating.

Senator Moody. What use has been made of any of those maps in the selection of irrigable lands in the Land Department?

Mr. Nettleton. I do not know that any use has been made of them.

Senator Moody. What sort of maps do they have to have, and what sort of work do they have to do, in order to segregate the lands under this last appropriation of 1888?

Mr. Nettleton. The only use of any map that I know of is one on which to make note of the lands segregated, the sections, etc.

Senator Moody. Do those segregations have to be made entirely independently of any topography?

Mr. Nettleton. Yes, sir; the segregations have to be described by township, range, section, and fraction of section, and have no connection whatever with topographic maps.

The **CHAIRMAN**. In order to make the segregation, it is necessary to make an actual survey on the ground, is it not?

Mr. **NETTLETON**. Yes, sir.

Senator **REAGAN**. Segregation for what purpose?

The **CHAIRMAN**. To ascertain what are and what are not irrigable lands. In order to accomplish that you would have to run a line on the ground any way?

Mr. **NETTLETON**. To connect that land with the present surveys?

The **CHAIRMAN**. With the Land Office surveys.

Mr. **NETTLETON**. Yes, sir.

The **CHAIRMAN**. If the topography were ever so accurate, it would not indicate the character of the soil, would it?

Mr. **NETTLETON**. No, sir.

The **CHAIRMAN**. And a line would have to be run to determine that?

Mr. **NETTLETON**. Yes, sir.

Senator **MOODY**. Would a topographic map indicate the character of the ground where the ditch has to be run?

Mr. **NETTLETON**. Only as to the slopes, but not as to whether it is sandy or alluvial soil.

Senator **MOODY**. It would not indicate whether the soil was rocky?

Mr. **NETTLETON**. It shows nothing except the slopes and the natural water courses.

Senator **MOODY**. In running the line of a ditch to carry water from a reservoir, would you or would you not take into consideration the character of the soil as to rocks and so on through which that ditch would run?

Mr. **NETTLETON**. Certainly we would have to consider that.

Senator **MOODY**. Would you not avoid, if possible to do so, in your engineering determination a region of country where the soil is composed of rocks, broken up or loose?

Mr. **NETTLETON**. I would avoid any country that would prevent the building of a practical ditch.

Senator **MOODY**. What use could be made of one of those topographic maps in locating the line of a ditch?

Mr. **NETTLETON**. In the actual location of the lines of ditches it would be of no use whatever.

Senator **MOODY**. In locating a reservoir, would you not take into consideration the character of the foundation of the banks?

Mr. **NETTLETON**. Yes, sir; certainly.

Senator **MOODY**. What use can be made of a topographic map for that purpose?

Mr. **NETTLETON**. It furnishes no information whatever in regard to the practicability of a dam site, or the character of its sides or bottom, which is one of the most important things to be considered in the construction of a dam. It simply shows what the slopes of the country are.

Senator **MOODY**. Can you not ascertain by the eye, with a sufficient degree of accuracy for engineering purposes, the location of reservoir sites preliminary to the actual and accurate survey?

Mr. **NETTLETON**. An engineer with good judgment can very closely estimate what is a reservoir site and what is not. He may not be able to determine whether it is entirely practicable. Perhaps the dam may cost too much for the amount of water it will hold. He can not determine those questions finally unless he makes a survey.

Senator **MOODY**. I mean, would you gather those facts by observation, preliminary to the actual and accurate detail survey?

Mr. **NETTLETON**. Most certainly.

Senator MOODY. Of what service would a good topographic map be in making those examinations?

Mr. NETTLETON. As I stated in the beginning, it might be of some assistance to an engineer who was a stranger in the country, by enabling him to get a general idea of the country; but in actually locating reservoirs, I do not think the topographic maps I have seen would be of any assistance.

Senator MOODY. Neither in locating reservoirs or in the line of ditches, nor in the segregation of the irrigable lands.

Senator JONES. Nor in the ascertainment of the sites for reservoirs.

Mr. NETTLETON. There are some reservoir sites that might be shown by such a map; for instance, take the one at El Paso. If there had been a topographic survey of that, with 20-foot contour lines, it would have shown without question that there was a reservoir site there; but there are thousands of other localities where 50-foot contour lines would not show nearly all the reservoir sites.

Senator MOODY. Will you please state any instance where the irrigation engineering service has reaped a benefit from the use of the topographic survey that has been going on?

Mr. NETTLETON. Well, I have had something to do with the starting out of two or three of the engineers on this survey. In the first place I sent to Washington (I was then at Denver) for all the maps of the country that was in my division. I had the Hayden Atlas, which survey covered Colorado, and I got some topographic maps of Arizona and New Mexico, and a few of Montana up about the Yellowstone. Now, I do not claim that I can read topography on a map as readily as some, but I looked those all over, and with one or two possible exceptions I could not find on any of them what I could safely say was a reservoir site, so that I could direct or recommend an engineer to examine it.

Senator MOODY. In the process of exploring and developing the possibilities of irrigation through the means of artesian wells, of what use will be the topographic work which is being carried on by the Geological Survey?

Mr. NETTLETON. I think that perhaps in connection with artesian wells it would be more useful than in the engineering work of selecting reservoir sites and dam sites, because those maps show approximately the elevation above the sea, and in studying an artesian country it is quite desirable to know the altitude of the surface of the country above the sea-level within a reasonable degree of accuracy.

Senator MOODY. In making those explorations and investigations what would the engineer have to do?

Mr. NETTLETON. Without a topographic survey he would naturally get the profiles of the railroads crossing the country, all of which have the elevations above the sea-level. From the railroad profiles it is possible to get the elevations at every mile, but you can always get them without a great deal of trouble at every town along the line of a railroad. These furnish a good basis to work on. I did a good deal of that work in 1868. Commencing in southern New York I carried it down through the oil region in Pennsylvania, and I worked up my surveys from the railroad elevations of the different stations.

Senator MOODY. Is that not entirely sufficient for making examination in regard to irrigation by means of water obtained from the artesian basins?

Mr. NETTLETON. If you had a series of contours carried all over the country, with benches established, that would be of great advantage over the railroad elevations.

Senator **Moody**. Is it essential in regard to practical demonstration?

Mr. **Nettleton**. No, sir.

Senator **Moody**. Can it not be done very much more cheaply without it?

Mr. **Nettleton**. Yes, sir.

Senator **Moody**. It would be a very expensive process to undertake to carry contour lines all over that semi-arid region 50 or 100 feet apart, would it not?

Mr. **Nettleton**. I do not know what the cost would be per square mile for such work. Do you, Mr. Bodfish?

Mr. **Bodfish**. From $1 to $5 per square mile.

Senator **Jones**. It would cost that for a topographic survey?

Mr. **Bodfish**. Yes, sir.

Senator **Moody**. Do you regard it as essential in making the examination for artesian basins throughout North Dakota, South Dakota, Nebraska, Kansas, and Texas, to have a topographic survey?

Mr. **Nettleton**. No, sir; I have been considering that subject, and have looked up the railroad lines crossing that country, and I find a great number of railroads, especially near the Missouri River, through the eastern part. There are several lines running east and west which give an excellent opportunity of getting the profiles of that region.

Senator **Moody**. So that you can make a pretty good guess as to the depths at different points of this artesian basin?

Mr. **Nettleton**. Yes, sir.

Senator **Moody**. Now, has it not been your experience, after all, that it requires the actual sinking of wells at different points to ascertain accurately the facts as to the depth of that basin?

Mr. **Nettleton**. Yes, sir; whatever data you find by a bore you know to be true; whatever you theorize on you do not feel so sure about.

Senator **Moody**. Is it not a fact that the roof of this artesian basin is very irregular, so that in some places you would have to sink very much deeper than in others, although at the same altitude?

Mr. **Nettleton**. In my study of the oil country I found a very uniform character of rocks 1,000 or 2,000 feet below the surface, but nearer the surface they were more broken.

Senator **Reagan**. If you were going to use the water of a particular stream to irrigate a particular plain, supposing there was no topographic survey or anything else to aid you, what steps would you take in order to apply the water to the land?

Mr. **Nettleton**. The first thing to be done is to determine what land you want to irrigate; the next thing to be done is to determine whether you have water that can be carried onto that land.

Senator **Reagan**. Determine the irrigation basin?

Mr. **Nettleton**. Yes, sir. Then, if there is more land than water, and money saving is an object, we seek the cheapest line, because the amount of irrigation that can be done is limited on account of the amount of water; so we pick out the most economical canal. But if it is the other way, if there is more water than land, and it is desirable to cover every acre of land, then we try for the highest line possible to get onto that land, without so much regard to expense.

Senator **Reagan**. What steps do you take to ascertain the extent and character of your catchment basin from which you get your water?

Mr. **Nettleton**. We generally take the maps of the country. That is one guide. Another is a knowledge of the character of the stream, obtained by observations or by inquiring of people who have known the stream for years, and who know about what its discharge is. For irrigation purposes it is not so much the size of the drainage area as i character that we rely on.

Senator **Reagan**. Do you regard it as essential to the success of suc an undertaking that you should know the extent of the drainage area

Mr. **Nettleton**. Yes, sir.

Senator **Reagan**. How would you get that?

Mr. **Nettleton**. I think in nearly the whole country in the ari region we have maps of some kind that give very closely the drainag system of the region. They are compiled, as far as they have been mad by the Wheeler, the King, the Powell, and the Government land su veys. These maps show quite closely the areas of the drainage basi of the streams.

Senator **Reagan**. Now, if there was a topographic survey made in th way that it is being made by the Geological Survey, could you not tak those maps and locate the drainage areas and the lands that are to b covered by water?

Mr. **Nettleton**. It would be relocating it. It would be simply con firming what has already been mapped; but I do not think that as t the areas it would change very much the areas of the drainage basin of the maps already made. It would give more information, perhaps, i regard to the slopes of the various parts of the country within thos drainage basins; but the exterior lines of the drainage areas would no be changed very much, I think, by a topographic survey such as is no being made.

Senator **Reagan**. Would you regard it as important, in determinin a drainage basin, whether it was a level or precipitous country, wit reference to the construction of your dam?

Mr. **Nettleton**. It would if a man went into that kind of work without looking before and around him, and if he had no idea of his own a to the country he was in; but when an engineer is sent into a country he can generally see pretty well its general character.

Senator **Reagan**. You think a good engineer could judge of the country without the assistance of the map?

Mr. **Nettleton**. He ought to.

Adjourned.

STATEMENTS OF CHEMISTS REFERRED TO BY ASSISTANT SECRETARY WILLITS.

UNITED STATES DEPARTMENT OF AGRICULTURE,
DIVISION OF CHEMISTRY,
Washington, D. C., February 3, 1890.

Hon. EDWIN WILLITS,
Assistant Secretary:

SIR: In addition to the information contained in the letter of May 7, which I hereby return, I would desire to call the attention of the committee to the fact that the character of the water used for irrigating purposes has much to do with the ultimate influence of irrigation upon the soil. If the water used for irrigating purposes contain much mineral matter, there would be a tendency for this matter to accumulate in the soil in such quantities as to become injurious to the growing crops. In many places where irrigation has been attempted with water charged with alkali it has had to be abandoned on account of the effect of the alkali mentioned above. Any attempt, therefore, to store water for irrigation purposes or to irrigate on a large scale should be preceded by a preliminary study of the nature of the water supply to be used.

The records of the Geological Survey abound in material of this description, that institution having made a systematic examination of the waters in the region embraced in the description contained in the committee's letter.

If the water, which is to be stored for irrigation purposes, come in the rain-fall it would usually be pure enough for irrigation purposes, provided it did not fall upon land already saturated with alkali. It is easy to see, however, that a body of water collected from the rain-fall descending on lands thoroughly charged with alkali might be wholly unfit for irrigation purposes. On the other hand, waters which are derived from large rivers and other streams are usually pure enough for irrigation purposes and could be used a long time on land without appreciably increasing the mineral constituents thereof.

Respectfully,

H. W. WILEY,
Chemist.

UNITED STATES DEPARTMENT OF AGRICULTURE,
DIVISION OF CHEMISTRY,
Washington, D. C., May 7, 1889.

Hon. EDWIN WILLITS,
Assistant Secretary:

SIR: Your communication of the 4th instant, addressed to Dr. Wiley, chief chemist of this division, has been referred to me for a reply, Dr. Wiley's trip to the West in the interest of the sorghum experiments preventing him from taking up the subject to which you refer.

I have examined the letter of Senator Stewart, which I return herewith, and have the honor to make the following report thereon:

That portion of the inquiry included under the character and constituents of soils seems to be the only point which falls within the province of this division. In order to enable you to furnish the committee with information which would be useful to them on this point, I have examined all the literature which is here available for information in regard to the constituents and character of soils west of the hundredth meridian of west longitude. I find several extensive investigations upon soils in this area and considerable information upon their character, and will make reference as follows to the sources where it can be found:

(1) The soils of the different districts in California have been made the subject of a very complete and important investigation by Prof. E. W. Hilgard, State chemist of California and professor of agriculture in the University of California. This investigation was undertaken for the Superintendent of the Tenth United States Census, and is embodied in volumes 5 and 6 of the Tenth Census under the head of "Cotton production." The investigation was intended especially to make comparison of the soils of California with those of the Southern cotton-growing States, with a view of investigating the adaptability of the California soils to cotton production. It comprises a large number of analyses of California soils taken from various localities, and a very complete and able discussion not only of the character and composition of these soils, but also of their geological sources and formation. The composition of soils of the various cotton-producing States is included in the investigation; also a

large number of analyses of soils in the Indian Territory. Further elaboration and discussion of the subject of California soils by Professor Hilgard will be found in the different reports made by him to the president of the University of California, notably in the reports for 1882 and 1884. Appendix No. 7 to the report for the year 1886 contains a valuable treatise by Professor Hilgard upon "Alkali lands, irrigation and drainage in their mutual relations."

I can commend the general plan and character of this investigation to the Senate committee as a model of the manner in which such an inquiry may be profitably carried on.

(2) The annual reports of the United States Department of Agriculture contain considerable information upon the subject of the composition of soils, and I have searched them through to obtain all the data upon soils in the region which forms the subject of the investigation by the Senate committee. The annual report for 1870 contains, on page 100, the analyses of three samples of soil from western Nevada. A special report of the Department of Agriculture, issued in 1882, entitled "Investigation of Sorghum as a Sugar-Producing Plant," contains on pages 58 and 64 analyses of a number of samples of soil from the Arkansas Valley in Kansas, namely, Great Bend and Hutchinson, Kans., and from Rising City, Nebr. In the year 1886 Bulletin No. 10 of the chemical division of this Department was issued, having for its subject "Principles and Methods of Soil Analysis," by Mr. Edgar Richards, assistant chemist. This publication contains the analyses of a number of soils, including prairie soils from Dakota, and also soils from Washington Territory.

Besides the above I would state that the chemical division is at present engaged upon the analysis of a large number of soils collected from different parts of the country, among which are included four samples of soil from Arizona, one from California, and three from the Territory of Wyoming. These analyses will be completed some time during the course of the present year, and the results can be communicated to the committee if they so desire.

(3) In addition to the above information on the subject of the character and composition of the soils within this region, it might not be improper to suggest to you that the attention of the committee be called to the sorghum plant as one peculiarly adapted to certain portions of the region which forms the subject of the committee's investigation. It might be well to forward to the committee, as part of the information to be furnished from this Department, the special bulletins containing the results of the experiments of the Department upon sorghum as a sugar-producing plant. Some of the best results in the growth of sorghum were attained last year in the southwestern portion of Kansas at the station of this Department at Conway Springs. Both these and previous experiments by the Department would seem to show that the sorghum plant is peculiarly adapted to the arid or subarid regions of the West. It resists drought much better than corn or the other cereal crops, and seems, moreover, to attain a higher percentage of sugar in these dry regions.

I would also respectfully call your attention to the report, upon which, however, I can give you no exact information, that the tropical sugar-cane is said to have been raised with considerable success during the past season upon irrigated lands in Arizona.

Respectfully,

C. A. CRAMPTON,
Acting Chemist.

MISCELLANEOUS PAPERS.

ESTIMATE FOR EXPENDITURES OF SURVEY.

DEPARTMENT OF THE INTERIOR,
UNITED STATES GEOLOGICAL SURVEY,
Washington, D. C., February 7, 1890.

DEAR SIR: Agreeably to a promise made you I herewith submit for your consideration an estimate of the cost of the field work of the Irrigation Survey for the fiscal year ending June 30, 1891, which includes the cost of doing the work and collecting the information that in my judgment is required by the law making appropriations for this specific work.

The estimate does not include the salaries of administrative officers above the Chief Engineer, nor the expenses connected with the publication of the necessary maps and reports, or the expenses for office rent in Washington and incidentals connected therewith.

After a careful consideration of the question regarding the time required to complete the surveys, and the ultimate cost thereof, I am of the opinion that five years will be ample time in which to cover the whole country with the necessary field work. Another year will be required to finish the office work and make the final field reports. In placing the time at five years I have endeavored to consider the immediate necessity for pushing the work with due regard for securing good results and with minimum expenditure of money.

I have designated the allotments for each State and Territory, but this may not be considered as at all arbitrary. This can also be said in reference to the total amount.

The semi-arid portion of our country needs something more than is contemplated in the present law. This section requires artificial water many times to tide over a few weeks of scanty rain-fall. There are no "waters in sight," and grave engineering difficulties present themselves when undertaking to supply it with the common methods for irrigation. There are several theories as to how the waters not "in sight" can be utilized. It is probably wise for the Government to undertake the solution of some of the most reasonable of these theories.

If the subject of climatological observations are to be taken up by the survey, as was suggested to the Senate committee at its last meeting, I would add at least $10,000 for this purpose.

If deemed wise, the appropriation could be made in bulk and then, if other considerations were to be taken into account, the expenditures could be locally changed.

I should suppose $75,000 would cover fully all unprovided salaries, office rent, the printing of maps, reports, etc., making in all $470,000. The appropriation for the first year will be larger than that for subsequent years on account of the purchases of instruments, field outfits, etc.

E. S. NETTLETON,
Supervising Engineer U. S. Irrigation Survey.

Hon. W. M. STEWART,
Chairman Senate Special Committee
on Irrigation and Reclamation of Arid Lands.

Estimate of the cost of the necessary surveys in compliance with the act of October, 1888, for the fiscal year ending June 30, 1891.

California	$50,000	Wyoming	$25,000
Oregon	15,000	Montana	25,000
Washington	15,000	Dakota (North)	10,000
Idaho	30,000	Dakota (South)	10,000
Nevada	30,000	Nebraska	10,000
Utah	40,000	Kansas	10,000
Arizona	20,000	Texas	5,000
New Mexico	50,000		
Colorado	50,000		395,000

GENERAL INSTRUCTIONS FOR HYDROGRAPHERS.

[The following instructions were issued by the chief engineer of the United States Irrigation Survey.]

The duties which devolve upon the hydrographers will be at once of a highly scientific and practical character, and will consist in ascertaining by systematic observations and measurements the values of numerous factors or qualities which must be known in order to fully carry out the purposes of the law, which requires an investigation of the extent to which the arid lands can be redeemed by irrigation. They may be mentioned in the following order:

(1) Measurements of water supply.
(2) Measurements of the loss of water by evaporation.
(3) The investigation of the climatology of the arid region with reference to agriculture by irrigation.
(4) Measurements of sediments transported by streams.
(5) The duty of water.
(6) Collection of general information.

(1) The measurement of water supply will consist primarily in the gauging of streams. For this purpose the methods developed at Embudo will be followed for the present, but with time and experience it is hoped that improvement will come. For this purpose stations will be established on streams to be gauged at points selected, and a systematic record will be kept of the rise and fall of the streams by means of inclined graduated rods, and the stations will be visited by the hydrographers so as to gauge repeatedly at different stations of the water until a sufficient number of stages have been gauged to admit of a formula for the stream and the s a tion. The stream beds will be plotted and the slopes ascertained by leveling. Full records will be kept by the hydrographers of all their gauging work and the results reported monthly to this office.

(2) This evaporation will also be measured by the general methods employed at Embudo. The quantity to be ascertained is the evaporation from water surfaces. Wherever practicable it is desirable to combine station work by placing evaporizaters at the same stations as river gauges; but this must be influenced by considerations of economy and the intelligence of the observers.

(3) The study of the climatology of the West will be mainly the work of the central office, as the data upon which it depends are of regional extent, and most of them are collated by the Signal Service, whose records are accessible only in Washington; but hydrographers are expected to furnish some accessory data, and to cultivate in their divisions the interest of volunteer observers and to promote the organization of meteorological societies. They are cautioned, however, not to duplicate the work of the Signal Service, but to maintain a most cordial and co-operative attitude towards the observers of that bureau and to conform to its methods.

Rain gauges will be placed at stations not occupied by Signal Service observers, and for the present localities at higher altitudes especially need investigating as to the amount of precipitation, and as a general though not invariable rule preference should be given to higher altitudes in choosing rain-gauge stations. It is deemed unadvisable to use the sling psychrometer except in cases where the observer is known to be a man of exceptional intelligence and skilled in the use of meteorological instruments.

(4) The measurements of sediments transported is a subject which must await future development, and no instructions can be given for the present with reference to it.

(5) Care should be taken to ascertain the duty of water in all localities where irrigation is practiced whenever opportunity occurs. The subject should be investigated personally, and too much reliance should not be placed on the mere statements of farmers unsupported by careful measurement. As the duty will vary, much inquiry is necessary to ascertain upon what causes such variations attend. The following factors seem to be of prime importance: (1) Method of flooding lands, (2) climate, (3) character of soil and subsoil, and (4) kind of crop raised.

(6) The central office will be frequently called upon to furnish information not only to Congress but to thousands of individuals throughout the country upon the subject of irrigation. In short, it must constitute itself a bureau of information. The hydrographers are expected to have their eyes open to all facts relating to irrigation and to keep the central office advised of everything of interest.

Reports must be made monthly, embracing a full account of all operations during the month. Records of gaugings, with the plates of the section at the station, and records of soundings and leveling must be kept by the hydrographers and copies of them furnished to this office at such times as will hereafter be stated and upon such forms as shall be prescribed. They will also collate the reports of the rain gauge and other observers and consolidate them, forwarding the consolidated report to this office.

EQUIVALENTS OF UNITS USED IN MEASURING WATER FOR IRRIGATION PURPOSES.

[Prepared by E. S. Nettleton, supervising engineer U. S. Irrigation Survey.]

UNITED STATES GALLONS.

100 gallons per minute equals—
.44 acre foot in 24 hours.
13¼ " feet in 30 days.
40 " " 3 months.
160 " " 1 year.
1 " foot in 55 hours.
.223 " " 1 second.
11⅛ California (miner's) inches.
8½ Colorado (miner's) inches.
1 United States gallon equals 231 cubic inches, or 1.748 cubic foot.

COLORADO INCHES.

100 Colorado inches equals—
5⅙ acre feet in 24 hours.
1 " foot in 4.2 "
155 " feet in 1 month.
465 " " 3 months.
1,860 " " 1 year.

THE SEEPAGE OF WATER.

EXTRACTS FROM THE REPORT OF THE STATE ENGINEER OF COLORADO FOR THE YEARS 1885 AND 1886.

[Filed by E. S. Nettleton.]

Seepage is a subject which is beginning to assume definite importance in connection with the economic use of water for irrigation; but it is only within the last year or two that any observations have been taken to accurately determine the volume in the stream above when canals are taken out and at a given point below. The amount returned to the stream by seepage through the soil was merely a matter of conjecture.

It is a well established fact that before irrigation became so universal in Colorado the water in the streams was greatly decreased in volume as it found its way out upon the plains. This was more particularly observed in the time of low water during the spring and fall season. Those who came up the South Platte Valley a few years ago will remember crossing the river in the eastern part of Weld County on the dry sand.

Within the last ten years at Platteville the river has vanished utterly at times, so that people could cross and recross dry shod. But there has been a change in this respect, and it has evidently been caused by the building of irrigating canals and the distribution and suspension for a time of the water upon and in the uplands adjacent to the streams. Observation and experience prove conclusively that seepage water is an important factor and adds largely to the volume of water flowing in the channel.

The increase in the lower valley of the South Platte has been a matter of notice, and becomes so distinct and certain that new canals have been constructed to take advantage of this interesting and important condition of affairs.

It is well known that the bed of Cherry Creek, once utilized as a thoroughfare for business in the city of Denver, has now a constant stream of water coursing through it, which is unquestionably the resultof seepage from what is commonly known as the High Line Canal of the English company.

In October, 1885, I instituted a series of measurements of seepage water in the Cache la Poudre, in order to obtain some accurate information upon this subject.

Five points of observations were selected, the uppermost being at the measuring flume in the cañon and the lowest at a point east of the town of Greeley, the two points being about thirty-five miles apart. A request was issued to the canal owners to close down the head-gates of all the canals, and so exclude all water; but in consequence of head-gates leaking, it was found necessary to measure the quantity which found its way into each canal and add this amount to that found flowing in the river in order to obtain the total discharge.

The following table shows the results of the measurements made October 12 and 13, 1885:

[Cubic feet per second.]

Places where measurements were taken.	Water in river.	Water diverted from river by canals.	Water in the river at the points measured plus that diverted by canals between those points.	Increase in volume of the river between the points measured.	Increase in river from the cañon to point measured.
First river measurement	127.06				
Pleasant Valley and Lake Canal		1.75			
Larimer County Canal		0.58			
Jackson Ditch		0.27			
Cache la Poudre Ditch		1.00			
Larimer No. 2 Canal		0.54			
New Mercer Canal		0.23			
Fort Collins Canal		1.14			
Second river measurement	134.00		130.47	11.88	11.88
Larimer and Weld Canal		1.73			
Judge Howes' Ditch		2.60			
Josh Ames' Ditch		0.69			
The Lake Canal		1.25			
Cache la Poudre No. 2		3.22			
Third river measurement	150.00		159.47	25.50	37.40
The Whitney Ditch		1.58			
Cache la Poudre No. 3		5.87			
Fourth river measurement	161.86		169.32	19.33	56.69
Ogilvy Ditch		38.96			
Fifth river measurement	153.12		192.07	30.21	86.90

The following table is made up from measurements made of the same river but four years later, or in October, 1889. These last measurements show that the seepage has been increasing since 1885.

Table of measurements of seepage water in the Cache la Poudre River, Larimer and Weld Counties, Colo., October 14 to 17, 1889.

[Cubic feet per second.]

Where measurements were taken.	Water in river.	Water diverted from river by canals.	Water in river at the points measured plus that diverted by canals between those points.	Increase in volume of river between points measured.	Increase in volume of the river from the gauging station at cañon to point where measured.	Increase in volume from gauging station at cañon to point where measured.

STATEMENT BY CHARLES W. GREENE ON FINANCIAL POLICY.

[Made by request.]

CHICAGO, ILL., *January* 20, 1890.

Hon. WM. M. STEWART,
United States Senator, Chairman Special Committee on Irrigation:

DEAR SIR: When in Washington a few days since you asked me to present in writing, for the consideration of the committee, my views in reference to the employment of private capital for the development of irrigation in the arid region.

You suggested that I should wholly discard the idea that the Government shall undertake the construction of any comprehensive and extensive system of reservoirs and canals, and that I should present—

First. The inducements necessary to enlist private capital.

Second. The practical safeguards against the monoply of the public domain by individuals or corporations.

Third. The protection which should be accorded to such investments.

Whatever value may attach to my opinions on these several subjects will be wholly due to the experience gained in almost two years of constant and reasonably successful effort to secure capital for corporate irrigation enterprises, and to the careful study of the subject which has been inseparable to such effort.

As to the first topic. The chief inducement to the investment of capital is the profit which may be directly derived from it. The first question asked is, Will it pay?

Those undertakings, considered as a class, which are proven by experience in different places and under varying conditions to have a reliable earning power, can command almost any sums of money that may be asked, at a rate of interest gauged by the risks incurred.

There must be, however, a public knowledge of such undertakings among the investing classes to command attention. While many investors insist on having personal knowledge of the management, or that it must be under their own eyes, others will take greater risks, provided the margin of profit is sufficient to justify. It is the latter class who will make most of the investments until a better knowledge of irrigation has been disseminated.

To state the difficulties may best suggest the requisites for success. The arid district is localized west of the ninety-eighth meridian, distant from money centers. It is but thinly settled and comparatively little known. There is a wide-spread prejudice, owing to the formerly prevalent idea that it was a "desert," unfit for cultivation and practically worthless.

There is not much of it that is inviting to the casual observer. The natural products are of slow growth; but few of them have any value as food for either man or beast. The tree-growth is shrubby and furnishes no desirable building material and but little fuel. The natural grasses, though nutritious, grow so slowly that as much as 30 acres is required to feed each animal ranging on them. It requires some courage, born of knowledge and experience, to invest money in the reclamation of such lands. Transportation facilities are limited. Settlements are few and far between. There is no inducement for settlement, indeed it is impossible until a water supply is provided.

It follows, then, that a first necessity is to let investors know the truth in regard to these lands. That they are exceptionally fertile. That the application of water makes them wonderfully productive. That the 30 acres which will now support only one animal becomes capable, when a water supply is provided and it is seeded with tame grasses, of feeding from sixty to one hundred animals. That the choicest fruits, and all the cereals, reach the highest perfection upon these apparently barren lands. That agriculture or horticulture becomes there an exact science. That water, sunshine, and soil may be combined by the intelligent cultivator for the production of as certain results as the manufacturer can attain from the combination of labor and the raw material in the various processes of industry.

Your committee has gathered a vast amount of reliable information that proves the value of these lands and the falsity of the popular impression, and which proves, too, the certainty of satisfactory returns for capital judiciously employed. The publication and general distribution of this information will, in my humble opinion, exert a most potent influence to secure the investment of private capital. It is a lack of knowledge which greatly delays such investments.

No greater inducement can possibly be offered than a statement of facts in regard to this region. The term "desert" is a misnomer as applied to such lands as water can be supplied for.

When compared with the granite hills of the East, with a scanty soil and a bleak climate, or even with the prairies of the central West, it has manifold advantages. There is a wealth of natural resources but little comprehended. There is money in the bright warm sunshine; there is money in the water wherever it can be brought and applied to the soil; there is money in the fertile surface soils; there is money in the clays; there is money in the timber; there is money in the vast coal-fields, in the extensive deposits of iron; there is money in the gold mines, in the silver mines, in the copper mines, in the lead mines; there is literally money in the underlying rocks. There is health and comfort in the dry, mild climate, in the mountain air, in the freedom from malaria and pulmonary ailments. These are among the inducements for investing money in irrigation and which will invite settlers to occupy every irrigable acre.

The area under discussion is of vast extent. It includes seventeen degrees of latitude and twenty-four degrees of longitude. The altitude varies from sea-level to about 8,000 feet. The temperature ranges from 40° below zero to 120° in the shade. The products embrace all those of the temperate zone and the subtropical fruits and grasses.

The sources of water supply are from running streams, from springs, and wells, from artesian wells, from tunnels into the mountains, from reservoirs retaining flood waters, etc. The distribution is by gravity through open canals and acequias, through cement and iron pipes at various pressures, or water may be raised or forced by wind, steam, or hydraulic power. The cost of water supply may range from a single dollar per acre to a hundred dollars or even more, and under certain conditions the latter cost may be justified by the returns.

Each locality has its specific advantages and favoring conditions. Experience has proved that irrigation enterprises have been successful in every part of this great area and under all of the varying local circumstances. But very few have been unsuccessful, and those were generally so from faulty management.

They are not all equally profitable. Some localities offer far greater advantages than others, and the most signal successes, as to financial results, have been achieved where the seasons are longest, where the sun shines hottest and most constant, and where vegetable growth is rankest.

The inducements to be presented to investors will necessarily be suggested by the conditions existing in each separate locality.

With a general knowledge of the underlying principles of irrigation, considered as an industry, widely disseminated, each undertaking will commend itself by its own peculiar advantages. These may be a specially fertile soil, a favorable climate, adaptation to particular products, a good local market, the facilities for transportation, cheapness of construction, an active demand for water which makes it command the higher prices, etc.

The security for such investments is exceptional. The increase in value of the land reclaimed is so positive and so rapid, and these values are so substantially based upon land with its earning capacity, that deferred payments and annual charges, as well as reasonable bonded indebtedness, are safe beyond all question. As compared with railroads, water-works, gas-works, or other corporate undertakings where the growth of traffic or patronage is comparatively slow and is contingent upon so many uncertainties, irrigating enterprises increase the values of land reclaimed often many fold within the brief time devoted to construction, and each item added to the income account becomes permanent and practically perpetual at agreed rates.

It will be very difficult to adapt general legislation to all the varied conditions which exist within the arid region of the United States. In Egypt the Nile is the one source of irrigation, and legislation may readily control every detail. In Spain or Italy the area is comparatively small in each, the climate is uniform, and all the conditions are similar, yet in these countries irrigation has presented many difficult problems for solution. It may be here noted that it is everywhere successful and profitable, and when once undertaken is never abandoned.

While the Wright law of California is admirably adapted to the needs of that State, where the lands are nearly all owned by individuals, the titles perfected, and all subject to taxation, where transportation facilities are excellent, and where all industries are well organized and specialized, it is wholly impractical for many localities, and particularly where there are large areas of unoccupied lands. In such localities the investment of capital must precede general settlement. The settler can not occupy or cultivate the land until provision is made for supplying water. The homesteader is not generally wealthy, and most of the localities where it is within the capacity of individual or community effort to secure and distribute water are already occupied and under improvement.

It is those districts where large streams must be diverted, where engineering difficulties are to be overcome, or where the water supply must be stored in expensive reservoirs which are now requiring large sums of money for their development. These are wholly out of reach for the land locator, and all the profit which could be derived under the most favorable circumstances from 100 or 200 acres of land would be small inducement for any man to inaugurate such undertakings. They are clearly beyond the capacity of individuals or communities. The individual can not live there, nor the communities be formed, until the large expenditure has been made and the water supply is actually provided.

Again, the municipal or public corporation system is impractical for such districts, because there is little, if any, taxable property. The homestead is not taxable until final proof is made, and that requires five years of actual residence. Pre-empted land is not taxable until a final receipt is issued, and that may be more than two years after settlement; and so with land taken under the timber-culture law or under the "desert" act, the title remains vested for a longer or shorter time in the Government, and the land is not subject to taxation during that time.

Whatever inducements may be offered to private investors to reclaim and make these lands inhabitable by direct legislation, it appears to me, must be in the way of providing some practical method by which capitalist and settler may co-operate. While the one shall make available a water supply he must be entitled to a fair and reasonable compensation, and the lands deriving a benefit should be held responsible for the payment. This regardless of whether the title remains in the Government after entry or has been perfected by the occupant.

A literal compliance with some of the present laws—which were never designed for the conditions under consideration—would render the construction of irrigation works almost impossible, and of necessity these laws have been construed with some liberality to the settler.

The embarrassments which must attend such legislation are manifold. It is variously estimated that from $80,000,000 to $120,000,000 are already invested in irrigation plants. They have been created under existing statutes, generally State or Territorial enactments. Though any proposed legislation should not be retroactive, any radical change might seriously affect present investments, as these undertakings require years of time for their development, and most of them are just at the beginning. Based upon enactments now in force and calculated upon existing conditions, they may be crippled or destroyed by adverse national legislation. Further investments would certainly be discouraged by injury to present investors.

Popular clamor denounces corporations and demands a scaling of the profits to be allowed capital; but such clamor is not always reasonable or just. The undertakings are too large for single individuals, and the aggregation of capital is only possible under the corporate or company system which has been devised for its concentration and employment and for the determination of personal liability.

Because there have been abuses of corporate powers is no good reason for the denunciation of a system which has accomplished so much that is beneficial.

A law which shall limit the profits of one party where the facilities are specially good and all conditions favorable, would destroy another less fortunately situated.

I shall therefore summarize as to the first topic:

There should be a general dissemination of reliable information to enable investors to judge intelligently as to the merits of the industry as a whole and as to particular localities. To this end the hydrographic and topographical surveys should be hastened. This is clearly within the province of the Government to provide. They need not be accurate and complete surveys, but rather preliminary, only presenting such general data as will determine the relative location of suitable dam sites, sufficient storage capacity and available arable lands, and as to what reservations are actually necessary. The extent of drainage area and average rain-fall should also be determined. There are not so many of these favorable locations as may be supposed. Indeed, they are comparatively few.

The area to be reclaimed is of such vast extent and there is such a variety of soil, climate, productions, of transportation facilities, of water supply and distribution, that national legislation may easily prove prejudicial.

The land laws should permit of co-operation between capital and settler. There should be positive assurance that the Government will not compete with nor embarrass private undertakings, though it may adopt all proper safeguards against the abuse of granted privileges.

With national legislation to protect the public land while providing for its occupancy; to determine as to suitable dam and reservoir sites; to prevent the occupancy of sites adapted to reclaiming and utilizing a large area by parties who only improve a fraction of it; to definitely determine the rights of appropriation of water limited to its use only; to grant the use of designated reservoir sites and right of way for canals and ditches on public lands, I submit that the legislation suited to each locality for the inducement and protection of investors can be properly and safely intrusted to the States and Territories.

The second topic: What are the practical safeguards against the monopoly of the public domain by individuals or corporations?

So much more is heard of the abuses of granted privileges than of the benefits derived that it is not unnatural if it creates an unfavorable opinion as to public honesty.

Yet it is quite safe to assert that the great mass of investors are really desirous of acting within the law. Obedience to and regard for the law is a necessity to the stability of investments. It is a small minority who are disposed to take advantage of their associates or of the Government. With the experience of the past as a guide it ought surely to be possible to guard against the schemes of the evil-minded without unduly restricting the operations of those who in good faith are willing to aid in creating wealth from the vast undeveloped resources of the region in question by the use of their capital.

There are four prominent methods under existing laws of acquiring title to the public lands.

The homestead law provides for a long bona fide residence and the payment of only nominal fees to acquire title. As I have before suggested, a homestead settlement can not very well precede a permanent water supply, and is only possible where the annual rain-fall will permit of some cultivation or will produce partial crops. It is, therefore, impracticable to adapt the present law to many large areas which it is possible and desirable to irrigate.

The pre-emption law requires a shorter term of actual residence on the land, but exacts $1.25 an acre in payment for it. This law has been taken advantage of and abused more than any other. If repealed as to the irrigable region it could probably be substituted by a better enactment.

The timber-culture law is objectionable in many respects, yet nowhere is there greater need to encourage the growth of trees for timber and fuel. If such encouragement could be provided for in some other way, or if it should be required of canal-builders, perhaps, as a condition to the granting right of way to plant trees along the main canals and principal laterals and on the margin of reservoirs, it would be of inestimable advantage to the public welfare. It would fully compensate the expense to the builders or owners of the canals by direct benefits.

The desert act has many good features and some bad ones. It gives inducement for the reclamation of the land by allowing the acquirement of a full section to each individual. It does not require residence either before or after the water is provided. The entryman may not be a resident either of the State or Territory. It does not stipulate as to what use shall be made of the land or how much shall be put under cultivation. It only requires that permanent water shall be carried to each 40 acres, and evidently assumes that when such expense has been incurred the self-interest of the entryman will prompt him to cultivate it. Under this law great abuses have been perpetrated, and yet it has some commendable features.

Can not a law be framed that will contain the good features of all these several laws and be the only one under which these lands may be acquired?

It may provide:

(1) For a reasonable limit of area.

(2) Prohibiting more than one entry to each individual, and defining the qualifications of an entryman.

(3) That the entryman may mortgage it to secure a water supply to a certain limit and to insure its maintenance.

(4) For a time limit within which the water supply may be secured.

(5) For actual residence and cultivation after water is obtained.

(6) For the perfection of title when certain improvements have been made or when a stated proportion has been brought under cultivation.

(7) For encouragement to tree-planting, not by the acre of solid growth, but by the number of thrifty trees, permitting the planting along ditches or fence rows and to include either fruit or forest trees.

(8) Severe penalties for the violation of its provisions.

As to the limit of area, it must in great measure depend upon the class and locality of the lands. While 5 acres of orange orchard, or other semi-tropical fruits, may afford a handsome income, 5 acres of land only adapted to grain or a single crop of grass would not be worth having. Whether the lands shall be classified, and who shall be authorized to make the classification, will require careful consideration.

The importance of rapid settlement and improvement of the reclaimed lands, and the advantage of having it occupied by the greatest number of occupants, is so great to a company providing water supply that it almost insures the exertion of every energy to that end. If, then, there shall be a limitation put upon the acquirement of extensive areas to be held for speculative purposes without improvement the returns to capital will be made dependent upon legitimate efforts.

A combination of the irrigable and pastoral lands has been strongly urged by Major Powell. Whether it can be practically accomplished throughout the entire region and under all circumstances is a question for very careful consideration. A limited area immediately adjoining a small tract of irrigated land could have no great value. Take the gramma grass districts as an instance. After each rain-fall the stem of this grass freshens and renews its growth. As the surface moisture is evaporated it dries and growth ceases until the rain falls again. It is equally nutritious, dry or green. It requires three years for a growth of 6 to 12 inches. If cut or fed close it may be months before it will again furnish pasturage. Under the present system of range feeding cattle can feed at any time over a range of 5 miles or more from permanent streams or springs. As soon, however, as a heavy rain or snow fall permits them to leave such permanent water they travel for long distances upon the plateaus or into the mountains. When one section is covered with snow they drift to another, it may be one side of a mountain where the snow melts soonest, so that localities many miles from permanent water are now utilized for pasturage. That these cattle must have access to the permanent water goes without saying, and the fencing in of such waters can not be permitted. If they are prevented from reaching the river they must have access to the canals or reservoirs. But if the pasturage shall be confined to the tract immediately adjacent to the irrigated lands many districts of plateau and mountain will be wholly worthless.

The third topic: What protection shall be accorded to such investments:

(1) A definite determination as to the rights which may be acquired in the use of water.

(2) Legal protection against subsequent locators who may seek to divert water supply where provision has already been made for its distribution for such reasonable time as will permit the settlement and improvement of the lands.

(3) A lien against the lands benefited to secure the payment of a just compensation for constructing the works and for their maintenance and for the use of the capital

invested, such lien only to apply as against the private ownership as acquired under the laws.

(4) Protection against malicious injury to the works and against the improper use or waste of water by the occupant of the land or others.

(5) Power to adopt and enforce such rules and regulations for the distribution of water as may be necessary to conserve and to facilitate its economic use.

The subject is very broad and of great importance, and I appreciate that in the brief time at my disposal and under the pressure of business engagements I have not been able to do it full justice.

REPORT BY E. M. McCLELLAN, C. E., ON ELKO COUNTY, NEV.[*]

Elko County, situated in the northeastern part of Nevada, is 155 miles in width, east and west, and 120 miles in length, containing 16,670 square miles of land.

About 30 miles south of the north boundary, extending across the county from east to west, is the water-shed, separating the waters of the Columbia and Snake Rivers from those of the great basin.

This water-shed is composed of several different parallel mountain ranges which trend north and south, having an elevation of 8,000 to 10,000 feet above the sea-level.

In many places the valleys between these ranges have such an even slope both ways from their highest part that it is only by close observation a person can determine when they have crossed the water-shed. At other points the ranges are connected by cross mountains, nearly as high as the main mountain.

On the north side of this water-shed are six main streams, viz: Goose Creek, in the east, Salmon River, Bruneau River, and the east, middle, and west forks of the Owyhee River. In the northwest corner of the county, lying between the east and west forks of the Owyhee River, is the Owyhee Desert, containing over 1,000,000 acres, 750,000 acres of which is fine agricultural land.

Four of the rivers now flow north, viz, the Salmon, Bruneau, and east and middle Forks of the Owyhee, which show distinct traces of having once discharged their waters in the opposite direction, and in the valleys at their heads can to-day be traced the shore-line of old lakes. At that time also the water-shed was farther north than now, and its course northeast and southwest. Subsequently the vast lava field, which covers Oregon, Washington, and Idaho, flowed up to and in some places over the divide. The consequent settling of the earth's crust beneath the weight of the lava caused an elevation of the country a few miles away from the edge; and also the convulsion which broke apart the mountain near by, and which are shown to-day by the deep, narrow cañons through which the rivers flow.

Upon leaving these cañons the rivers have worn away the lava to a great depth, and now flow across the desert in precipitous gorges from 200 to 3,000 feet in depth. Where the mountains end and the lava field commences, the rivers are very near the level of the desert and can be readily carried over it. And in each of these cañons, which are not over 100 feet wide at the bottom, dams can be placed turning the valleys again into lakes, and the water, now running to the ocean, will be utilized in reclaiming land, which is the richest and most productive in the world, but, as it now lies, is worthless.

As most of the agricultural lands lying below the old lake beds on the Salmon and Bruneau Rivers and Goose Creek are in Idaho I will not report on them, but will mention a small lake bed, near the head of the Salmon (No. 18), which can be reflooded and 20,000 acres reclaimed in this State, and one on Goose Creek (No. 19) which will irrigate 10,000 acres.

Upon the east fork of the Owyhee are two reservoir sites, Nos. 16 and 17, on appended plat.

No. 17 is at the upper end of the ancient lake bed and can be utilized in irrigating 4,000 acres of land below it, which will not be covered, by a reservoir 100 feet high at No. 16.

No. 16 will flood about 10,000 acres at the lower end of the old lake bed and store sufficient water to irrigate 150,000 acres of land. It has 220 square miles of natural water-shed, some of the mountains being 10,000 feet high.

No. 15 is an old lake bed, now called Bull Run Basin, and is the finest small reservoir site in the country. It has about 50 miles of water-shed, is surmounted by high mountains, and water can be stored for 50,000 acres.

---

[*] This report did not reach the committee in season to be inserted in the third volume of testimony.

Report on Irrigation.

No. 14 is in the southern part of the State; same lake bed as 15, the mountain having been broken open in two places, but the site for a reservoir is not good. It is separated from 15 by a ridge 100 feet high.

No. 13 is the old lake bed near the head of the main Owyhee, and has a drainage of 270 square miles. The storage capacity and water supply is amply sufficient for 250,000 acres.

The Little Owyhee, heading west of Elko County and flowing across the northwest corner, has a small lake bed near its head, not shown on the accompanying map. The waters stored in these reservoirs, Nos. 13, 14, 15, and 16 and on the Little Owyhee, can by canals be conducted upon the lava field at the highest places and conveyed over all the land which water can be collected for. The necessary canals leading out from the cañons and constructed along the base of the mountains would also gather all the water coming from the mountains in the small streams which flow down. The early spring flow from these streams alone will irrigate at least 50,000 acres during the flow, which lasts till July.

Heading in the water-shed and flowing south into the Great Basin are a large number of fine streams, the largest of which flow through ancient lake beds, which can be converted into reservoirs. Commencing on the west, the first one is the Little Humboldt River, which rises upon the southern crest of the lava belt, flows north 18 miles, then west and southwest. There are no lake beds along its course until after it enters Humboldt County.

Rock Creek flows south through two old lake beds, each of which will be easily flooded. The first, No. 12, at the lower end of Squaw Valley (the present name of the old lake bed), has a drainage of 400 square miles. There are only about 10,000 acres of agricultural land in Elko County below this reservoir site. The second, No. 11, 12 miles below the first, in Rock Creek Basin, and partly outside this county, has an additional drainage of 200 square miles.

About 200,000 acres of good agricultural land lies below these two in Eureka, Lander, and Humboldt Counties, a part of which can be reclaimed by these reservoirs.

No. 9 is another lake bed, situated just outside of this county. It is not as good a reservoir site as any of those so far named, but has a fine water-shed of 250 square miles on Maggie Creek. About 10,000 acres can be reclaimed by this.

No. 10, on Susie Creek, is a small reservoir point; has a water-shed of 50 square miles, with 3,000 acres of good agricultural land below.

The north fork of the Humboldt, with its tributaries, flows through five old lake beds. Nos. 2, 4, 5, and 6 are comparatively small, and will flood about 2,000 acres with dams 30 feet high. No. 3 is the largest and most important in the county south of the water-shed. The old lake bed covers nearly 10 square miles, drains 750 square miles of territory, and will irrigate 100,000 acres of land which lies below it.

No. 7, near the head of Mary's River, on Hanks Creek, is also an important reservoir site. It has 50 square miles' drainage of mountains 9,000 feet high, and nearly 200,000 acres fine agricultural land below it.

No. 8, at the head of Bishop Creek, is a second-class reservoir site, with a drainage of 75 square miles.

No. 1 is the only lake bed that can be used on the south side of the Humboldt River, and a very important one, as into it can be put the drainage of 700 square miles, covering the highest mountain range in the State of Nevada (the Ruby Mountains, which are 13,000 feet high). A dam here 100 feet high would cover 10 square miles, but it would take one at least 200 feet high to hold all the water now going to waste. There are at least 1,000,000 acres of agricultural land below in the Humboldt Valley.

These lake beds, from Nos. 1 to 12 inclusive, lie in the Humboldt Basin. In addision to these, which are away from the main river, there are three places in this county where the river has broken through mountain ranges—at A1, A2, and A3—where are fine sites for large reservoirs but impracticable on account of the railroad and towns in the valley. They also mark the sites of old lakes which were several hundred feet in depth.

A1, at the junction of the north fork with the Humboldt River, is the largest. A2, below the mouth of the south fork, is second in size. A3, in the western part of the ounty, at the mouth of Maggie Creek, is third in importance. The break through he mountains below A3 forms the Palisades, noted as the finest bit of scenery along he overland railroad.

Below each of these reservoir sites is sufficient land to be irrigated with all the water that can be stored in it.

The Humboldt River is the most important river in the Great Basin, having nearly ,500 miles of water channel. The entire water-shed of this river lies in Elko County, xcept two tributaries of the Little Humboldt in the northern part of Humboldt ounty, and Reese River, in Lander County, which flows north through the central art of the State.

The river in its course southwest, after leaving Elko County, flows across one ther larger lake bed than any of those above, and breaks through another chain of mountains at Iron Point, between Battle Mountain and Winnemucca. Battle Mountain is built within this lake bed, and contains the only artesian wells that have been sunk in the eastern part of the State. Reese River enters the Humboldt Valley at this point.

Through Elko County the Humboldt River bottom is about a mile wide. On each side are bluffs from 50 to 100 feet high, and extending back from these bluffs to the foot of the mountains on both sides lie table lands, upon which the few farmers in our county are located, and where all crops raised in the temperate regions can be grown and harvested with far less work than in the countries not irrigated. At the present date the farms are located along the small streams where they come from the mountains, and where the only work necessary for reclaiming the land was to clear off the brush at a cost of $2 an acre and run a plow furrow from the creek upon it.

Only one reservoir has been built in the county. It is located in Squaw Valley, in the western part of the county, and a canal in connection with the reservoir has reclaimed 5,000 acres. The company expect to irrigate as much more by it as soon as the land can be cleared off. This land without the water was worthless, now it is worth $100 an acre. The cost of constructing the dam and canal was $200,000. Cost of 5,000 acres of land cleared and planted was $25,000, which leaves a gain of $275,000.

The cost of the next 5,000 acres will be only $25,000 which will net the company owning it $475,000.

The reservoir site, utilized by them, is poorer than any which I have mentioned as yet, being the only one which the company could utilize for their land. There are a large number of reservoir sites throughout the county as good as the one utilized in Squaw Valley.

In the northeast corner of the county the water-shed has turned north to within 12 miles of the north boundary, and on the south slope is the headwaters of Thousand Spring Creek. The north branch, called Rock Creek, heads here 25 miles west of the Utah line and flows south 20 miles. The South Fork, or main Thousand Spring Creek, heads 35 miles south and 25 miles west of the head of Rock Creek, flowing northeasterly to the junction.

Just below the junction the mountain has been broken through, and above it is the reservoir site, marked No. 20 on the appended map. These creeks drain 450 square miles of water-shed, one-third of which is mountain land. Twelve miles below this, one, at No. 21, is another lake bed, which can be utilized, but the opening where a dam would be built is nearly 300 feet wide. It has 125 miles of additional water-shed. Below these two reservoir sites is 125,000 acres of fine valley land.

The waters of Thousand Spring Creek and all east of the Ruby range of mountains belong to the eastern part of the Great Basin in which Salt Lake is situated. In the southeastern part of the county the mountain ranges are lower than elsewhere and the precipitation of moisture far less. The prevailing storms are all brought from the Japan current in the Pacific Ocean, northwest of us, and the water-shed on the north and Ruby Mountains on the west catch most of the moisture as the clouds go over them.

There are two ranges of mountains in this section, with valleys between, which have no outlet and were lake beds at some period of greater precipitation than now.

Between the Ruby range and the first range east the valley is divided into two parts. The southern part, lying close to the Ruby Mountains, is called Ruby Valley. It is 5 miles wide at the lower end and 12 at the upper. At the south are two lakes—Ruby and Franklin. The Ruby range is low at the south, furnishing comparatively little water, and Ruby Lake is fed by numerous springs which overflow from the artesian belt beneath, created by the ancient lake. Franklin Lake, just north, and about the same level as Ruby lake, is supplied from the surface streams which flow into it and Franklin River.

Ruby Valley is 50 miles long. Northeast of Ruby Valley is the northern part of the main valley, which is subdivided into two valleys, called Clover Valley and Independence Valley.

Clover Valley lies on the east of the mountains, which is here generally called Clover Mountains. The valley is 20 miles long and 10 miles wide. East of Clover Valley is Independence Valley, 40 miles long and 10 wide.

These two valleys once formed a lake of greater extent, but have now less precipitation of moisture than Ruby Valley.

Just south of Independence Valley is Spruce Mountain, which has an elevation of 10,000 feet but is only 3 miles long on the summit. East of the south end of Ruby Valley are the north ends of Long and Butte Valleys; across the mountains lies Steptoe Valley. It is divided into two parts, the northern part lying in this county and being 60 miles long and an average width of 10 miles; it is called Goshute Valley. The ancient lake bed in this valley is more extensive than in the valleys west of it, but at the present day the precipitation of moisture is far less. All of these valleys show the presence of artesian belts beneath, but no wells have ever been sunk and it is not known what supply they will furnish.

There are no good reservoir sites in this section of the county, and although there are over 1,000,000 acres of fine agricultural land in these valleys, not over 200,000 acres of this can be irrigated without a large expenditure for storage. The Ruby and Clover range have sufficient snow and rain-fall to irrigate all the land in the valleys if it was stored.

The reservoir sites thus far described are the largest and best in the county, will need an average expenditure of $100,000 each, and the work can only be done by the Government or capitalists. Twenty of the twenty-one mentioned have an outlet where the dam would be placed less than 100 feet wide, and a dam 100 feet high would not be over 700 feet long at the top.

The bottom and sides of the cañons are, in all cases, solid rock, and stone for building can be quarried on the spot. The land to be irrigated below them still belongs to the Government. Nearly all the land in this county taken up is on the low bottoms along the rivers and streams that were natural meadows, where the ground is too damp and cold to raise anything but grass.

Owing to our poor transportation facilities and an unjust discrimination against the whole State by the only through line of railroad in it, the farmers have been only able to raise cattle for the markets abroad. The consequence is that in selecting land the first necessity for the settler was to find a piece of meadow where he could at once raise hay for his stock. Then if by a little work he could clear off and cultivate a small garden to raise enough vegetables for his own use he had to be contented.

Before the railroad was built connecting the mining town of Eureka, in Eureka County, with the Central Pacific Railroad the people had a good market for their produce, and farms were taken up and vegetables and cereals grown for that market along the slope of the Ruby Mountains. Upon the construction of the railroad and a combination of the two roads produce of all kinds were shipped from California and the East cheaper than the farmers could land it in town. For a number of years grain was shipped from California to Eureka for $10 a ton; at the same time if a Nevada farmer living near the railroad wished to ship his grain to Eureka he would have to pay $30 a ton. On all other farm produce the same unjust discrimination is used.

This has nothing to do with the amount of agricultural lands and reservoir sites in our State, I know, but it accounts almost entirely for the lack of advancement we have made. Neither capital nor settlers are attracted to a place where they know exorbitant rates will be charged them for everything that can not be raised but must be shipped in; where, when anything is raised, the rates for importing the same thing is lowered till it can be sold within a few miles at a less price than it can be raised and landed to the market for; and where, when a market for the produce is found away from home, the rates are raised till it will not pay to ship it. These are the actual facts in this State, and because of this the people have been confined to the raising of cattle and horses, which could be sent to market without depending upon the railroad.

The interstate law has helped us some, but there still remains high rates which only a competing line of railroad will overcome.

A close estimate of the land in this county shows that we have nearly 2,500,000 acres of No. 1 agricultural land and about 1,500,000 acres of this can be reclaimed by a proper storage and distribution of water. In doing this the reservoirs so far mentioned only form the principal points for storage. There are hundreds of small reservoir points where a small expenditure of capital and work will create a storage of waste waters capable of irrigating from 100 to 10,000 acres of land each.

In calculating the agricultural acres I have only put in my estimate those lands in the county where it appears the best results could be had. I have left out nearly 1,000,000 acres which have a rich soil but which lie in small tracts not easily reclaimed compared with the rest. When this State has the population which its vast mineral wealth and unrivaled climate will some day bring to it, most of this land will also be utilized.

As I have stated before most of the lands taken up lie along the river and creek bottoms and are too cold and damp to raise anything but hay. Along the Ruby Mountains is the largest exception to this rule, and it is here that most of our farmers have settled. Here at an elevation of nearly 6,000 feet above the sea-level can be raised all the products of the temperate regions, including grapes, peaches, cherries, apples, and small fruits as well as all the vegetables and cereals.

The climate is so healthy that there are only four doctors in the whole county, and most of the cases they have are caused by accident and not from disease.

Of this 2,500,000 acres of good land, only 90,000 acres is under irrigation to-day, and 60,000 of this is natural meadow, leaving only 30,000 acres actually farmed. All lands that are to be reclaimed are farming lands, being dry and warmer than the bottoms. A very liberal estimate to be placed upon the cost per acre for storage of the water and canals for conveying it upon the lands would not be over $20. The cost of clearing it off ready for cultivation would not be over $5 per acre more, making a total cost of $25.

In the northwestern part of the United States, along the Pacific coast, where immigration is now directed, the actual cost of clearing the land and getting it ready for cultivation is $135 per acre. The land is no richer, the climate far inferior, and the amount of work to harvest a crop nearly double what it is in this State.

There is also in all non-irrigating regions the liability every few years of drought with consequent loss of crops or excessive moisture with equally bad results. Here the farmer can tell before planting, even without storage, exactly how many acres can be irrigated each year, and, supplying the growing crops himself with just the amount of water needed for each product, he never misses a harvest, and the produce of his fields and orchards is fully equal and in many cases superior to those of non-irrigating countries.

The traveler crossing our State sees only the worst sections of the eastern part. The line of the railroad along the river bottom under the bluffs is 50 feet or more in elevation.

Looking from the car window he can see in the distance the mountains covered with perpetual snow, and can imagine that there must be streams flowing from them, but he does not see the miles of rich table lands intervening, across which flows from April to June sufficient water to convert every acre of it into productive farms if held in reservoirs until needed.

No measurement of the annual flow of water in the numerous streams in the county of Elko is known, but the farmers who have been in the country the longest state that they are positive the quantity of water flowing to waste every year is amply sufficient to irrigate every acre of agricultural land in the county. If this be true, it would bring 3,500,000 acres under cultivation instead of 1,500,000 as I have estimated.

The agricultural land and the water to irrigate it lie in close proximity in this northern part of the State. The only thing necessary to create a fertile and populous county out of the seeming desert, is wise legislation founded upon a just appreciation of the needs of an irrigation district.

All enactments of our law-makers, since the organization of the United States, have been founded upon the English common law, acknowledged to be the best in the world, and as long as we had only a country to make laws for which did not need irrigation the English riparian act was the one needed for that country. But now we have a vast empire of arid lands for which an entirely different code of laws is required, and to successfully meet these requirements it is absolutely necessary to frame laws of a character wholly unprovided for by English common law. To do this it is not necessary that experimental enactments be passed as though irrigation was a new thing in the world.

The experimental stages of law-making for the successful reclamation of arid lands have been passed through by other governments, both in the new world and the old, and all we have to do is to adopt the best of these, or compile a code of laws from the best parts of all or some of them with the very slight changes which might be necessary to their introduction into a free country.

The main point upon which the successful solving of the irrigation problem depends is the absolute ownership and control by each State government of all waters, storage points, and right of way for main feeding and distributing canals. The State could then construct the canals and reservoirs and rent the water (as done by other governments) at rates determined by the cost of constructing and keeping in repairs the necessary works.

No time should be lost by the Government in securing all the water and storage points in the arid regions. The history of other irrigating communities should be sufficient for us to be assured that only evil will befall any section of our country where one of the main elements of life is the property of any individual or corporation and can not be controlled by the people.

Our agricultural lands lie at a general elevation of 5,000 to 6,000 feet above the sea-level. Our mountain ranges have varied elevations of from 7,000 to 13,000 feet in height. Very few observations have been taken of the amount of rain and snow fall at different elevations in the country, and at only one place have we any data for a Series of ten years past.

At this place (Camp Halleck), situated at an elevation of nearly 6,000 feet, the main precipitation for the ten years was 10.5 inches annually. That is the general average of precipitation also over a large part of the agricultural lands of the same general elevation, but it nearly all falls in the winter and spring and has mostly disappeared before the irrigation season is over. This amount of precipitation is greater than in many places in the United States where irrigation is unknown.

The precipitation in the mountains can only be estimated, but it can not be less than three times that of the valleys.

STATEMENT OF ARNOLD HAGUE, GEOLOGIST, U. S. GEOLOGICAL SURVEY, IN RELATION TO THE NATIONAL YELLOWSTONE PARK AS A WATER RESERVATION.

In the organic act of 1872, establishing the Yellowstone Park, Congress declared that the reservation was "dedicated and set apart as a public park or pleasure ground for the benefit and enjoyment of the people." The wisdom and foresight of those who at that time urged the withdrawal from settlement of this tract of land from the public domain has never been questioned.

The necessity for the protection of the geysers and hot springs and other unrivaled scientific curiosities of the region, the importance of utilizing the park as a game reservation for the larger Rocky Mountain animals rapidly becoming extinct with the settlement of the country, and the natural advantages of the place as a sanitarium and health resort, have since been recognized by the steadily increasing crowds of visitors who annually visit the place.

From these æsthetic points of view alone the value of the Yellowstone Park to the nation have amply repaid for all cost of maintenance. Its advantages to the nation in the future has scarcely begun to be realized even by those most familiar with its charms and natural advantages. Notwithstanding all that may be urged in favor of a liberal maintenance of the Park based upon sentimental considerations, the most forcible argument for its preservation is an economic one far outweighing all others in benefits to the people.

In my opinion the object of first importance in maintaining the Park is the conservation and regulation of its water supply. By the natural configuration of the country the Park is singularly adapted as a catchment basin for the storage of water. It is doubtful if any region of the same extent in the arid regions of the Rocky Mountains offers so many favorable conditions for receiving, storing, and distributing through a few main drainage channels so large an amount of water.

The Park is situated in the extreme northwest corner of Wyoming, and covers an area approximately 50 by 40 miles. The central portion of the Park is an elevated volcanic plateau between 7,000 and 8,500 feet above sea-level, with a mean altitude of 8,000 feet. The surface of the plateau is diversified by undulating basins of varied outline cut by numerous deep cañons and gorges. Strictly speaking, it is not a plateau in the popular acceptation of the word; at least it is by no means a level plain, but a rugged country presenting bold escarpments, the edges of mesa-like ridges. Rising above this plateau on the south, east, north, and northwest occur mountain ranges whose culminating peaks tower from 2,000 to 4,000 feet above the inclosed table-land.

The Gallatin Range shuts in the Park on the north and northwest. Spurs and outlying ridges of the Gallatin connect it with the Snowy Range, an elevated mountain mass which bounds the Park on the north and pours a large share of its water into the Yellowstone River. The Absaroka Range borders the Park along the entire eastern side and presents for more than 80 miles an unbroken barrier to all western progress. It is an exceptionally rugged region with volcanic peaks and table-topped masses rising from 10,000 to 11,000 feet in height. Only a few adventurous hunters and mountaineers cross the range by one or two dangerous, precipitous trails, known to but few. The early trappers found it a forbidding land; prospectors who followed them, a barren one. The Absaroka Range, however, furnishes one priceless treasure: from its western slope it sends numerous torrents into the Park, many of them running directly into Yellowstone Lake. On the east side of the range an equally large water supply make up the Stinking Water and Clark's Fork, which ultimately flow into the Yellowstone River. The Absaroka Range is intimately connected with the Wind River Range, which shuts in the plateau on the south. To the westward, and separated only by the broad valley of the Upper Snake, lie the Teton Mountains, whose northern outlying spurs project into the Park. On the southwest side of the Park is situated the Madison Plateau, which stretches northward until it abuts against the southern end of the Gallatin.

From this incomplete sketch it will be seen that the Park country, although a high table-land, stands relatively low to the rugged mountains which surround it on all sides. From this outer rim of mountains innumerable streams pour their waters into the Park.

Across the plateau from the southeast to the northwest, but with a very irregular course, runs the Continental Divide separating the waters of the Atlantic from those of the Pacific. On both sides of the Continental Divide and within a few miles of the line, lie a number of large bodies of water which form so characteristic a feature in the scenery of the plateau that the region has received the appellation of the lake country of the Park. Hundreds of smaller lakes lie dotted over the surface, filling irregular depressions in the lava flows or occupying shallow basins scooped out by glacial ice. Many of these lesser lakes are found as natural reservoirs higher up in the mountains. In addition to these are found numerous ponds, marshes, and meadows everywhere scattered over the country. So numerous are they that the water held by them adds a very considerable amount to the total water supply. Two rivers, the Yellowstone and Snake, receive the greater part of this water, the former draining more than one-half the area of the Park and the latter the entire western side of the Continental Divide. Falls River, a very considerable stream in the southwest corner of the Park, empties into Henry's Fork before its waters join the main Snake River. On the north side of the Divide both the Madison and Gallatin drain large areas of the Park, the former, running westward, cuts through the Madison Plateau, while the Gallatin, although receiving none of its water from the Park plateau, still carries off a large amount of water precipitated upon the reservation. Both these latter streams unite with the Jefferson in Montana to form the Missouri.

Let us examine a little more closely into this water supply. I can not do better than to quote from an article on the physical features of the Park which I published not long since.

"Yellowstone Lake, the great reservoir for the river which gives its name to the Park, is a body of water of great beauty, measuring 20 miles in length, with a breadth across its greatest expanse of 15 miles. It has a very irregular outline, with an indented shore of nearly 100 miles, and an area of 140 square miles. Not only is the Yellowstone by many times the largest lake in North America at so high an elevation above sea-level (7,741 feet), but it ranks among the first in the world at high altitudes. Upon the western side of the Divide, less than 6 miles from the Yellowstone, and separated from it by a ridge not more than 200 feet in height, lie Shoshone and Lewis Lakes; the former with an area of 12 square miles, and the latter 4½ square miles. Heart Lake, at the eastern base of Mount Sheridan, measures 3 square miles. These three smaller reservoirs pour their waters into the Snake, which also finds its source near the southeast corner of the Park.

"In the autumn of 1886, with a view of obtaining some data upon the amount of discharge, the largest bodies of water were accurately measured. Not only was the time selected the driest period of the year, but all lakes and streams stood at a lower level than at any time during the previous five years. Yellowstone Lake stood 20 inches below the high-water mark of early summer. The measurements may be said, therefore, to have been taken at the minimum discharge. Measured just below the outlet of the lake the discharge of the Yellowstone River was found to be 1,525 cubic feet per second, or, in other words, 34,000,000 imperial gallons per hour. The out-flows from Shoshone, Lewis, and Heart Lakes combined yielded 104 cubic feet per second. The Lamar, Firehole, Gibbon, and Madison Rivers were gauged, and careful estimates made of the Gallatin and Falls Rivers, based upon the size and flow of the streams and the area of the country drained. According to estimates of Dr. William Hallock, of the U. S. Geological Survey, who kindly undertook the gauging of the streams, it was found that the minimum discharge was equal to 1 cubic foot per second per square mile over an area somewhat more than 4,000 square miles, and that the amount of water running into the Park and leaving it through the five main drainage channels would make a river 5 feet deep and 190 feet wide, with a current of 3 miles per hour. While this may not indicate a large supply as compared with certain highly favored areas, yet it is for the arid region of the West an exceptional amount."

While there are many conditions governing both the amount of snow and rain fall in the far West, two important factors are found in the Park region which influence in a large measure the precipitation of moisture. These are the great elevation of the culminating peaks surrounding the Park, and the exceptional broad mountain mass. From Madison Valley eastward across the Park and the Absaroka Range the country attains an elevation unsurpassed by any area of equal extent in the northern Rocky Mountains. For 90 miles in an east and west line the country rises in a solid block far above the adjacent country, admirably situated to act as a condenser for the moisture-laden clouds. Meteorological records taken for a number of years show a climatic condition unlike that observed elsewhere in the Rocky Mountains, the amount of snow and rain fall being higher and the mean annual temperature lower. Rain-storms occur frequently throughout the summer, while snow is quite likely to fall any time between September and May. In an arid region and one of unequally distributed rain-fall, forests and moisture maintain reciprocal relations. The abundant precipitation over the Park exerts a favorable influence upon forest growth, 84 per cent. of the area being timber-covered. This forest in turn protects the snows and marshes from the intense heat of the sun and the dry westerly winds. By means of this protection the deep snows of winter lie upon the plateau well into midsummer, while at still higher altitudes in sheltered places it remains throughout the year, slowly supplying the springs and streams.

By its topographical structure the Park is designed by nature as a reservoir to collect an exceptional water supply. By its geological structure it is well adapted to store this water, both on the surface and in the deeply buried rocks. From beneath the lavas of the plateau numerous streams and underground springs pour their waters into the lakes and out upon the land surfaces.

For these reasons the present area should be enlarged to the east and south so as to take in a dense forest region useless for agricultural purposes and destitute of mining resources, but embracing a rough, mountainous country abounding in streams—the real sources and feeders of Snake River, Yellowstone Lake and River. The area proposed to be added to the Park would extend the boundaries about 25 miles to the eastward and 9 miles to the southward of the present ill-defined limits which were established at a time when the region had been but little explored. The proper control and distribution of the water is a necessity to the people of Montana, Dakota, Wyoming, and Idaho. The protection of the forests, game, and marvels of the reservation should be the desire of every one looking to the welfare of the country. The interests of the Park should be zealously guarded by the nation.

REPORTS ON IRRIGATION

FROM

CONSULS OF THE UNITED STATES

CORRESPONDENCE WITH STATE DEPARTMENT.

UNITED STATES SENATE,
Washington, D. C., April 23, 1889.

SIR: Referring to your letter of the 2d instant, in which you state that "our consuls will be instructed to prepare reports covering such phases of the subject (namely, irrigation) as you may be good enough to intimate," I inclose herewith a draught of a letter which if you will have sent to our consuls in the countries mentioned in the inclosed memorandum where irrigation is practiced, will greatly oblige the Senate Committee on Irrigation and Reclamation of Arid Lands.

Please forward all reports received by you to Mr. R. J. Hinton, Engineer, U. S. Geological Survey, Washington City.

Yours, respectfully,

WM. M. STEWART,
Chairman Committee on Irrigation, etc.

The SECRETARY OF STATE.

DRAUGHT OF LETTER IN REGARD TO IRRIGATION TO BE SENT TO CONSULS.

WASHINGTON, D. C., *April* 23, 1889.

The questions connected with irrigation and the reclamation thereby of arid lands are now attracting public attention. Congress has recently made appropriations for surveys of reservoir sites, ditches, canals, etc., and the United States Senate has created a special committee to thoroughly investigate the general questions involved. The Department, in response to an inquiry from the special committee, desires to aid in its investigations, and therefore requests as early as practicable a report on the subject of irrigation as practiced in the country in which you are stationed. Your inquiries should be directed in the main to the following points:

(1) Areas of land under irrigation; compare with the non-irrigable and cultivable areas when possible. Also quantity and quality of crops grown.

(2) Sources of water supply, whether from rivers, streams, springs, lakes, wells, reservoirs, catchment basins, or tanks, etc.

(3) Character of works used for storage and distribution of water. Forward published reports, if obtainable, in regard to any important irrigation and storage works.

(4) The system of water distribution, whether governed by laws, rules and regulations, or customs. Give duty of water per acre, *i. e.*, the amount used per acre and per season, the cost or rental to user;

tenure of ownership of water, and whether the same be public or private, national or community.

(5) Character of climate in irrigated region and nature of soil, annual rain-fall or other precipitation.

(6) Antiquity or otherwise of irrigation systems within the section treated of, and whether the same are maintained at public or private expense.

The Department desires to obtain maps and any publications obtainable bearing upon this subject for the use of the Senate committee.

The committee states that it desires to place itself in communication with competent experts and authorities on irrigation. These investigations should be conducted diligently, and reports made as early as possible.

MEMORANDUM FOR DISTRIBUTION.

All Asiatic countries: Egypt, Tripoli, Tunis, Morocco, Algiers, Senegambia, Orange Free State, Colonies of Cape of Good Hope and Natal, Madagascar, etc. Also, Madeira, the Azores and other islands, the Australian Colonies, Hawaii, South and Central American Republics, the Empire of Brazil, Mexico, and European Colonies of South America. The principal countries of Europe in which irrigation is practiced are France, Italy, Spain, Portugal, Holland, Turkey, Greece, Austria; also Russia in Asia.

MEXICO.

REPORT BY UNITED STATES CONSUL JOHN WOESSNER, OF SALTILLO, ON IRRIGATION IN COAHUILA, MEXICO.

A part of this section of this large and rich State is irrigated from springs which generally rise in the mountains; the water is carried in many cases and often many miles from these springs to level, fertile land by means of narrow ditches. Other parts of this State, the lands can not now be irrigated on account of no water, and the total absence of the necessary implements for boring and the proper practical labor to accomplish the required result. Where there are springs the water should be carried through iron tubes; farther away from here, where there are no springs, but "haciendas" of importance, the artesian well, it seems to me, is what is needed. I would advise manufacturers in the United States who desire to build up a trade of this kind to do so with a direct representative who speaks the language, establishing an office centrally located in the Republic, where attention may be given to the wants and demands of such a trade.

Water is worth a great deal more than land in this country, and the right to use it is fixed by laws. Much good land is not used because of lack of water, and to depend on rain in some parts is too much of a risk. With a good water supply much of the rich soil of this State would produce abundantly of nearly all kinds of products, which at present are not enough to support the population.

There are very few windmills used at present in this State, though I think they might be successfully used, for the reason that good winds blow nearly all the year. There is considerable water-power unused, which, according to law, can be acquired by denouncement. If a spring of water rises in the property of any one, the owner of the property also owns the spring. Rivers are owned and controlled by the State through which they pass. Rights and privileges to public waters are sold by the State.

The system of water distribution is as follows and is generally acquired by purchase: A stream of permanent water is called thirty days of water and the owner may sell the right to any one to use this water for any length of time; say, for example, one day in every month, which is called one day of water, worth very often as high as $1,000 per day. It is an understood right between all land owners that parties owning any right or privilege in the water can pass same to their land through the lands of adjacent owners by means of narrow ditches. This system often causes many difficulties, particularly when the owner of a day or two of water dies and leaves some fifteen or twenty heirs, each of whom receives his share in hours, being an equal division under the same right of the day or two of water inherited. The formation of artificial lakes has already awakened attention, and a foreign company of capitalists agitates at present the question of making a lake with the waters of the Rio Grande, to be used for industrial and agricultural purposes. This project, however, involves difficulties, arising from its international character.

REPORT BY U. S. CONSUL A. WILLARD.

UNITED STATES CONSULATE,
Guaymas, Mexico, August 14, 1889.

Up to the present time the lands cultivated in Sonora (this consular district) are confined to the bottom or valley lands on the small streams and rivers.

For the purpose of irrigating said lands dams of simple construction of stone and earth, or brush and earth, are erected on the sides or in the streams, and ditches are dug to convey the water to the lands cultivated. These dams, as a rule, require repairs and some reconstruction each year.

The ditches require cleaning and repairing yearly, but are not expensive to maintain.

REPORT BY U. S. CONSUL-GENERAL C. C. MORE, CITY OF MEXICO, ON IRRIGATION IN MEXICO.

The system of irrigation has become very generally practiced in various portions of this republic, having been in vogue more or less ever since the days of the conquest of the country by the Spaniards in 1521.

It may be stated as a general proposition that the natural supply of water in Mexico is very limited as compared with that of other countries. The traveler in this republic notices the great scarcity of rivers, running streams, lakes, and springs. In the mountains of the country many small streams take their rise, but soon after reaching the plains they become absorbed in the sandy soil and sink into the ground. Again, in Mexico during the rainy season there is a great abundance of water (said rainy season may be stated, in a general way, as extending from June 1 to October 1), but for the remainder of the year the rain-fall is very scant, water becomes very scarce, and the whole country becomes very dry, except in the regions along the sea-board (the

Pacific Ocean, the Gulf of California, the Gulf of Mexico, etc.), in which localities the dews are very heavy and refreshing showers much more frequent than in the upland regions.

I will now take up the six points of interrogatory mentioned in your circular, and incorporate in my replies the information obtained from the said department of public works and from other sources:

(1) "Areas of land under irrigation; compare with the non-irrigable and cultivable areas when possible, and quantity and quality of crops grown."

Answer. The department aforesaid assured me that they had no statistics upon which to frame an answer to the first part of this question, and that it would take months to collect the information in proper shape.

The principal crops grown here with the assistance of irrigation are sugar, coffee, corn, wheat, oats, barley, beans, cotton, and tobacco; also oranges, bananas, and other fruits. Without irrigation, except near the coast, the yield would be very meager; with irrigation said crops are excellent, and will compare favorably with those of other countries, especially when consideration is had of the primitive agricultural implements used and the inefficient cultivation as contrasted with that practiced in the United States, England, France, and Germany.

(2) "Sources of water supply, whether from rivers, streams, springs, lakes, wells, reservoirs, catchment basins, or tanks, etc."

Answer. The water supply for irrigating purposes is drawn principally from rivers, streams, and natural lakes. In some instances bold springs gush from the earth and furnish a constant, never varying supply for irrigation of thousands of acres, as in the case of "Atlacomulco," in the State of Morelos, a large, beautiful "hacienda," or plantation, at one time owned and operated by Cortez, the Spanish conqueror, and still belonging to decendants; on the hacienda of "Coakinstla," one of the finest sugar plantations in Mexico, near the city of Cantla. Sometimes also large dams of solid masonry are constructed at great expense, which, however, form large reservoirs of water during the rainy season, and which during the remainder of the year furnish the necessary supply for irrigation. Artesian wells supply some of the water used for irrigation; also wells from which the water is raised and poured into the irrigating canals by means of windmill pumps and buckets attached to an "endless chain," which are kept in motion by mule or horse power.

(3) "Character of works used for storage and distribution of water. Forward published reports, if obtainable, in regard to any important irrigation and storage works."

Answer. The works used for storage and distribution of water consist of dams constructed so as to elevate the level of the water in streams and rivers where they can not be tapped by the aqueducts and irrigation canals at sufficient elevation to reach the destined fields of cultivation; also large reservoirs are formed, as above stated, through the instrumentality of massive dams, generally of stone masonry, the water being collected during the rainy season and held for use when needed.

(4) "The system of water distribution, whether governed by laws, rules and regulations, or customs. Give duty of water per acre, *i. e.* the amount used per acre and per season, the cost of rental to user, tenure of ownership of water, and whether the same be public or private, national or community.

Answer. As a part answer to the fourth interrogatary, the department of public works handed me a copy of the decree of June 5, 1888, which I herewith have the honor to inclose, accompanied by a translation of the same into English.

Each State of the Republic has its separate laws and regulations regarding the distribution of water. The duty ot water per acre, or the amount used per season per acre, varies according to the quality of the soil, climate, and plants under cultivation. Moreover, the cost of water is generally included in the rental paid for the lands, which varies exceedingly in different places, according to the peculiar circumstance attending each locality.

The ownership of the water is both public and private, but generally the latter, as the water privileges, being considered of quite as much value as the land itself, have in many instances been transferred or transmitted by inheritance along with the title to the land.

(5) "Character of climate in irrigated region and nature of soil; annual rain-fall or other precipitation."

Answer. The climate of the irrigated region in this country corresponds to the climate of the different States of the Republic, as in all of them there exist irrigated lands, with this general statement, however, that on and near the sea-coast the climate is much warmer and the rain-fall much greater than on the table-land and in the mountain districts.

As a further answer to this question, the said department of public works furnished me with a copy of the geographical, statistical, and descriptive study of Mexico by A. Garcia Cubas, special attention being called to the seventh and eighth chapters, relating respectively to hydrography and agriculture.

The nature of the soil embraces every variety known to the country, from the light, sandy soil of the table-lands to the rich, dark alluvial of the valleys and the fertile, black loam of "the tierras calientes"—the hot countries.

In regard to the annual rain-fall, said department handed me the tenth number of the monthly bulletin of the meteorological, magnetic, central observatory of Mexico in which is published a report on the rainfall in different parts of the Republic, running through a number of years; also a table containing a comparative résumé on the subject for the years *et seq.* to 1888, and both of which, in deference to the request in said circular, I have the honor to herewith transmit—

(6) Antiquity, or otherwise, of irrigation systems within the section of, and whether the same are maintained at public or private expense.

Answer. The antiquity of the various systems of irrigation in Mexico varies with the different localities, they having been constructed and put into operation not simultaneously, but at different epochs, as the different sections became more or less cultivated by intelligent labor and the necessity of irrigation became apparent. As a general proposition, however, it may be stated that said systems date all the way from the early part of the sixteenth century when the Spaniards took possession of the country, introducing their splendid system of irrigation as rapidly as they began the cultivation of the various localities.

The department of public works further assures me that none of said irrigation works are maintained by public funds.

[Translation.]

[Department of public works, colonization, industry, and commerce. Third section.]

The President of the Republic has thought fit to direct to me the following decree:

Porfirio Diaz, constitutional President of the United States of Mexico, to its inhabitants makes known:

That the Congress of the Union has decreed the following:

ARTICLE 1. There shall be considered as general, public highways, besides the inland roads, railways, etc., to the effect of section 22, article 72 of the constitution, the following:

The territorial seas, marshes, and lagoons situated on the sea-coast. Canals constructed by the Government or by means of public money. Interior lakes and rivers, if navigable. Whatsoever lakes and rivers situated and serving as boundary lines between this Republic and other foreign nations or between two States.

ARTICLE 2. The Federal Executive has the power and right to look after the aforenamed public roadways and to regulate the private and public use thereof, according to the following basis:

A. The towns situated on the sea-shore or banks of a river shall have the gratuitous use of the water necessary for all domestic purposes of its inhabitants.

B. There shall be respected and confirmed the rights of private individuals relating to the use and profit of rivers, lakes, and canals, providing that said rights consist in lawful titles or civil prescription exceeding ten years.

C. The concession or attestation of rights or titles to private parties on the lakes, rivers, and canals relating to the present law, can only be made by the department of public works, excepting the case where said concession shall change or threaten to change the course of the rivers or canals aforenamed, or should deprive of the use of their waters the inhabitants living down the stream.

D. The rights of fishing and pearl-diving on the territorial seas and the uses and profits of marshes and lagoons situated on the sea-shore or national vacant lands, shall be regulated specially by the executive power.

ARTICLE 3. All transgressions of the law comprised in the common jurisdiction committed on interior lakes, canals, or rivers, as well as the controversies that may arise between private individuals, relative to obeying the statutes issued by the department of public works, shall be submitted to the competent local jurisdiction.

MEXICO, *May* 28, 1888.

Miguel Castellanos Sanches, senator president; Luis C. Cariel, deputy president; Guillermo de Landa y Escandon, senator secretary; A. Riba y Echeverria, deputy secretary.

Therefore, I order it shall be printed, published, and circulated, and that due compliance shall be given it.

Signed in the palace of the executive power of the Union, in the City of Mexico, on this 5th day of June, 1888, Profirio Diaz. For General Carlos Pacheco, secretary of State, and the department of public works, colonization, industry, and commerce. I recommend it to you for your knowledge and corresponding efforts.

Liberty and constitution.

Mexico, June 5, 1888.

PACHECO.

CUBA.

REPORT FROM OTTO E. REIMER, U. S. CONSUL, ON IRRIGATION IN THE CONSULAR DISTRICT OF SANTIAGO DE CUBA.

Before answering the questions propounded in your circular of May 2 it would be well to enumerate in brief the reasons which render irrigation in this consular district almost unnecessary. I say "almost unnecessary" because all the crops, such as sugar, cocoa, coffee, plantains, and other crops of minor importance, are dependent on the changes of rainy and dry seasons in this tropical climate. This consular district is well watered by rivers and small streams which irrigate the rich and deep alluvial soil under cultivation. The largest river, the Canto, which finds its source in the Sierras del Cobre, a mountain range to the westward of this city, and after a tortuous and winding course during which it receives various tributaries, empties into the sea 14 miles north of the town of Manzanillo. This river, choked up at its mouth by drift-wood and sand bars, is about 180 miles long, of which 60 are navigable. Captain General Salamanca has caused studies to be made in view of forming a plan to make the mouth of the river navigable, thus opening a water-course which traverses some of the most fertile districts of this province. The Canto, with its tributaries, constitutes the water system of the south coast of this province. Between the Capes Maisi and Cruz the coast line is very mountainous and only small streams find their way to the sea.

The north coast is full of larger and smaller rivers which find their way into the numerous and large bays. Notably the Mayari, Naranjo, etc. So artificial irrigation has as yet not become a necessity excepting, to my knowledge, only in one instance. Messrs. Brooks & Co., an English firm here, owning a sugar estate on the bay of Guantanamo and called "Los Canos," have been compelled, owing to the curious fact that although sufficient rains fall near and around the estate very little falls on its territory, to introduce an artificial system of irrigation. This system of open ditches irrigates about 10 caballerias (333⅓ acres) of cane fields, and as just commenced I cannot give you the results. The water for this system is procured from the Guantanamo River, which is dammed above the area irrigated and the water distributed by a system of canals. The system was instituted after the necessary permission was obtained from the Spanish Government; is a private enterprise, and pays neither rental nor taxes.

The amount of water used per acre depends on the rain-falls of the rainy season and can not be estimated, as the work has just commenced. The character of the climate is tropical and the annual rain-fall, in the absence of all scientific observation, I would estimate at 45 inches.

CENTRAL AMERICA.

REPORT OF U. S. CONSUL-GENERAL JAMES P. HOSMER, GUATEMALA, ON IRRIGATION THEREIN.

In reply I beg respectfully to state that there is no system of water distribution for arid lands in Guatemala.

The practice of irrigation, in the very limited extent to which it obtains, is that of ordinary ditches fed from the nearest water source.

REPORT OF U. S. CONSUL CHARLES H. WILLS, OF MANAGUA, NICARAGUA, ON IRRIGATION.

There is not, nor has there ever been, as far as I can learn, any system whatever of irrigation.

Wear Nandaime, a small Indian town in the department of Rivas, three cacao (chocolate) estates are partially flooded in a primitive way by their owners from small rivers or streams being dammed to cause the water to flow over the plantations, which are below the streams. No system is practiced.

SOUTH AMERICA.

REPORT OF WINFIELD S. BIRD, U. S. CONSUL, LA GUAYRA, ON IRRIGATION IN VENEZUELA.

The subject of irrigation, to which the attention of consular officers is directed by circular instruction from the Department of State, dated May 2, 1889, is one upon which very meager information can be furnished from Venezuela; for although, in a crude way, irrigation is practiced to some extent, yet there are no available statistics to offer in reference to the areas of land under irrigation, and no means of comparing these with the non-irrigable and cultivable lands. Of the small area of cultivated lands in this consular district, exclusive of those planted in coffee, perhaps the greatest part is devoted to sugar-cane; and, from personal observation, it would appear that the crop generally needs more cultivation and irrigation than is usually given it.

The small streams coming down from the mountains form the only supply of water for the purposes of irrigation, and in a tropical climate like this the volume of water is so often reduced during the long and hot summer season that the supply proves inadequate, and consequently the crops suffer to a greater or less extent. The present season has proved quite disastrous in this respect, so much so that crude sugar, usually sold at 10 cents per pound, is now worth 25 cents per pound. The importation of cane products being prohibited by law, it seems that the use of sugar and its compounds, so general in this climate, must be greatly curtailed, and, to many of the poorer classes, entirely cut off.

The character of the works used for the storage and distribution of water are of the simplest description and consist of ordinary dams and trenches. There are no irrigation and storage works of any importance, every process of this nature being conducted upon the most inexpensive and antiquated plan. It is no doubt true that even the Chinese are, in this respect, far in advance of these people in the various appliances and processes for irrigation; and it is equally true that if a more careful and provident system were adopted, much of the water that now goes to waste might be utilized for the reclamation of arid unproductive lands.

The system of water distribution is governed, according to the best obtainable information, by custom only, although there are some statutes in reference to it that, by common consent, have fallen into disuse. The unwritten law is that each person shall have the right to water on a stated day for a certain length of time, when he must close his flood-gate and again await his turn. Under such an arrangement, therefore, it is evident that the amount of water used per acre and per season and the tenure of ownership, etc., can not be intelligently stated.

Everything connected with the subject of irrigation in Venezuela is of such primitive character that it can be of no special interest in the elucidation of plans and processes for use in the United States. No maps nor publications with any reference to it can be obtained or even heard of, and it appears that the subject has never received the slightest degree of the attention that its importance to the agricultural interests of the country so seriously demands

REPORT OF O. McGARR, U. S. CONSUL-GENERAL, GUAYAQUIL, ON IRRIGATION IN ECUADOR.

(1) A very small quantity of land is under irrigation in Ecuador, not the thousandth part of the cultivable land. No grain crops are grown on irrigated land, which is used only for pasturage and for raising alfalfa in small quantities. An infinitesimal part of the arid region, which is extensive in northern Ecuador, is under irrigation.

(2) Small rivers, mountain streams, and springs are the source of the water supply. There are no basins, reservoirs, or tanks used.

(3) There are no works constructed for the storage of water. Its distribution is by ditches. No reports on the subject have been published in this country.

(4) The system of water distribution is governed by custom, except in the few instances where water is carried over the land of adjoining proprietors. In such cases the law regulates and defines the rights and duties of the owner of the easement and of the servient estate. I have no means of ascertaining the amount of water used per acre or per season. It is not measured and it is not rented. The water used for purposes of irrigation belongs to the individual land owner using it. There is no national, municipal, or community ownership.

(5) The climate is that of the winter-Andean region with an average maximum temperature, with shade, of 62 to 68 degrees, the average minimum being about 54 degrees. In some localities the soil is a sandy loam and in others a dark, heavy clay, and very deep. The rains are ordinarily confined to the months between the middle of December and the first of June, and are quite copious in most seasons. I can not state annual rain-fall.

(6) Under the Spanish rule there was something of an irrigation system, regulated by laws, and at the time of the Conquest there was a better and more extensive system than has existed since. That now in use is maintained entirely at private expense.

REPORT FROM J. GRIERSON, U. S. CONSUL, COQUIMBO, ON IRRIGATION IN THE PROVINCE OF COQUIMBO, CHILI.

This province is in a very backward and primitive state as regards cultivation and irrigation, on account of the country being very barren and mountainous, the only cultivation being along the valleys running down between the mountains which convey the snow-water from the Cordilleras. Hay and barley are the principal productions, the former, when green, being eaten on the ground by cattle.

Water is supplied by canals or large ditches cut at different places rom the rivers of snow-water, as mentioned above. Each canal, rom its leaving the river until it reaches the sea, belongs to the owners f land along the upper part of which the canal flows.

No works are made for stowage of water. When the river is full the luice doors to the canals are open all the time, and water is suplied in abundance; but in years when there is little snow on the ountains, and consequently the river low, the sluices are opened, as rranged by the canal committee.

Each canal has a president and a committee, elected from the cursors, ho superintend repairs, allowance of water, etc. The value of a farm epends on the number of inches belonging to it; each proprietor of nd can buy or sell any or all the number of inches of sluice he has a ght to draw from the canal, each inch being worth about $3,000 (gold) and is the same as tangible property. A sluice-wall 15 to 20 inches makes a good farm worth about $3,000 to $4,000 yearly.

The climate is good and very mild. Up the valleys grapes, oranges, and pears grow well, and by irrigation five crops of hay may be cut yearly. From 1872 to 1880 the rain-fall was only 3½ inches per year; latterly, with intermissions, it has been about 7 inches yearly.

The rivers are, of course, under Government control, but the canals are private property and from time immemorial have been superintended and kept in order by their owners. Every town, however, is entitled to a proper proportion of water.

REPORT FROM W. T. WALTHALL, U. S. CONSUL, DEMERARA, ON IRRIGATION AND DRAINAGE IN BRITISH GUIANA.

No systematic irrigation exists in this colony. The need of it is felt when the dry seasons are protracted beyond their ordinary limits, but in such cases the only methods employed to water the crops are of the simplest and most primitive description—by manual labor, without the aid of machinery of any sort. The system of drainage, however, and of the employment of artificial water-ways for the transportation of produce and plantation supplies is elaborate, costly, and extensive. Although not strictly pertinent to the information sought by the Department, the subject is somewhat akin, and a brief account of it may not be irrelevant.

In order to understand the conditions, it must be borne in mind that the rich agricultural region of the colony consists in general of the lowlands adjacent to the sea-coast and the tidal parts of the larger rivers. These lands are several feet below the level of the highest tides, for which reason it is necessary to protect them from overflow by a continuous line of embankments, or "sea-dams" as they are termed.

This cultivable region extends back from the beach and the banks of the lower rivers to a distance varying (by a rough estimate) from 2 to 5 or 6 miles, when it meets what is termed, in the language of the colony—perhaps not very correctly—"the savanna" or "bush" lands. This is a belt of country between the rich coast lands and the hills and forests of the interior, slightly more elevated than the former but lower than the latter, partly open and partly covered with trees, vines, and shrubs, but everywhere abounding in swamps, ponds, and creeks of fresh water.

The estates of the colony are laid off on the plan adopted by the original Dutch settlers and still existing in its main features. They are divided by parallel lines, approximately perpendicular to the line of coast, and forming long, narrow, and somewhat irregular quadrilaterals, which would be parallelograms but for the sinuosities and irregularities of the coast line. The unit of measurment of distance is the Rhynland rood, still in habitual use, of 12 feet 4 inches. The original width of each grant was 100 roods, or nearly a quarter of a mile, and the length or depth from the sea-dam 750 roods, or about 1¾ miles. Such is at this time actually the extent, inland, of the only lands owned in fee-simple, though many of the estates have been extended toward the "savanna," or including parts of it, by grants of possession and occupancy at the pleasure of the Crown, supposed to be practically equivalent to ownership. Many of the original estates have also been united and some of them divided, though the regular parallelism of their side boundaries is still maintained.

In order to protect these estates from overflow in the rainy seasons by the waters of the swamps, ponds, and streams of the "savanna," "back-dams" are erected in the rear of the cultivated area. On the lines of division between the estates canals or trenches are dug for drainage, the earth thrown out from these constituting material for embankments, known as "side-line dams," which also serve as road beds for walking or riding. Smaller cross-drains connect with these side-line trenches.

Besides the trenches for drainage, another system of trenches or canals is employed for the internal navigation of the estate. For this purpose a canal is generally dug through the estate, the excavated earth forming alongside of it an embankment known as the "middle walk." Cross-canals extend transversely from this toward the boundaries of the estate but stopping short of them, so as not to communicate with the side-line or drainage trenches, the terminus of the navigation cross-canal forming a sort of *cul-de-sac.* These canals are used for the transportation, by flat-bottomed barges or "punts," of the crops, fertilizers, etc., in one direction or the other.

These canals are supplied with fresh water from the swamps, creeks, ponds, and in some cases artificial reservoirs of the "savanna," the water being admitted and the supply regulated by means of water-gates, or "kokers" as they are termed, in the back-dams. Stronger and more elaborate kokers are employed in the sea-dams, which are opened at low tide to permit the discharge of the drainage and other fresh water, and closed at high tide to hinder the influx of the sea water.

The coast lands of the colony consist of a stiff clay, interspersed with veins of sand and covered with a superficial layer of vegetable mold or "pegass." The clay being impervious to the percolation of water is very favorable to rapid drainage from the surface.

The chief staple is sugar, though there are some cocoa-nut plantations, and in certain parts of the colony large estates, or "cattle-farms," are devoted to pasturage.

I have spoken of artificial reservoirs. The advantages of these in regulating the varying supply of fresh water during the wet and the dry seasons are obvious. Besides those already existing, others are projected on a still larger scale.

The cost of the works required for drainage and the supply of water to the towns, villages, and estates is assessed on the proprietors and others interested, though they are controlled and regulated by the Government. The money is frequently advanced by the Government with the understanding that it is to be repaid by taxes on the property for the benefit of which it is expended. This, of course, does not apply to the works undertaken by proprietors for the special benefit of individual estates. In some cases, also, participation in the burdens and benefits of public or corporate enterprises is to some extent optional with the individuals interested.

The climate of the colony is torrid, but remarkably uniform, the extremes of temperature being about 73 and 90 degrees Fahr. The average is about 81 degrees. The average annual rain-fall is estimated at about 100 inches.

REPORT FROM E. L. BAKER, U. S. CONSUL, BUENOS AYRES, ON IRRIGATION IN THE ARGENTINE REPUBLIC.

I am in receipt of the circular of the Department of State of the 2d of May last, stating that the question of reclaiming the arid lands of the United States is now attracting the attention of our Government, and instructing me, in aid of its inquiries, to report on the subject of irrigation in the Argentine Republic, and especially directing my attention to the areas of land under irrigation, the sources of the water supply, the nature of the works, the system of distribution, the character of the climate, the annual rain-fall, the antiquity of the works, etc.

ANTIQUITY OF IRRIGATION IN SOUTH AMERICA.

In regard to antiquity, I have to say that the artificial watering of the earth to increase its fruitfulness is of so remote an origin in South America that its history is quite unknown. It has been generally assumed that the practice had its beginning in the Orient; and we know that in the days of the patriarchs various contrivances for flooding the fields and meadows were in general use. It was not, however, until the end of the seventeenth century that water meadows were constructed in Europe upon anything like a scientific system; and only towards the end of the eighteenth century that any great improvement took place in this branch of agriculture. In South America, on the contrary, it is evident that a scientific system of flooding, which consisted in spreading a sheet of water over cultivated fields in such a manner that it could be readily withdrawn was not only practiced by the aborigines of the country from the most remote periods, but that it was done with an amount of precision and knowledge which even to this day are matter of wonder to those who inspect the remains of their works.

It seems hardly possible that the natives of Peru and Bolivia, and of the eastern slopes of the Andes, which now constitute a part of the Argentine Republic, could have acquired their skill from the nations of antiquity beyond the Atlantic; and hence we are at a loss to understand how such a people, without a long-previous civilization, far in advance of their condition when their Spanish conquerors arrived, could not merely have solved the problem of the artificial watering of the land to increase its productiveness, but constructed aqueducts and reservoirs to that end, on such an immense scale and in such an enduring manner that they have defied the changes and vicissitudes of unnumbered centuries. When they were built we do not know; but their remains abundantly prove that the inhabitants from an unknown date were well versed in many of the ways and means of civilized life; that they pursued husbandry and practiced agriculture on scientific principles, and that, in defiance of the general absence of rain, they succeeded in providing bountiful harvests even on the precipitous sides of the sterile sierras. The historian of the conquest of the country refers to the knowledge of agriculture possessed by the primitive inhabitants and the wonderful works of irrigation constructed by them in such a manner as to prompt me to make a quotation from his pages. He says of the "ancient works":

> Much of the country suffered for want of water, as little or no rain fell, and the few streams in their short and hurried course from the mountains exerted only a very limited influence on the wide extent of territory. The soil, it is true, was for the most part sandy and sterile, but many places were capable of being reclaimed, and indeed needed only to be properly irrigated to be susceptible of extraordinary production. To these spots water was conveyed by means of canals and subterraneous aqueducts executed on a noble scale. They consisted of large slabs of freestone nicely fitted together without cement, and discharged a volume of water sufficient, by means of latent ducts or sluices, to moisten the lands in their lower level through which they passed. Some of these aqueducts were of great length. One that traversed the district of Condesuyu measured between 400 and 500 miles. They were brought from some lake or natural reservoir in the heart of the mountains, and were fed at intervals by other basins, which lay in their route along the slopes of the sierra. In their descent a passage was sometimes opened through rocks, and this without the aid of iron tools; impracticable mountains were to be turned; rivers and marshes to

> be crossed; in short, the same obstacles were to be encountered as in the construction of their mighty roads.
>
> Most of these beneficent works of the incas were suffered to go to decay by their Spanish conquerors. In some spots the waters are still left to flow in their silent, subterraneous channels, whose windings and whose sources have been alike unexplored. Others, though partially dilapidated and closed up with rubbish and the rank vegetation of the soil, still betray their course by occasional patches of fertility. Such are the remains in the valley of Nasca, a fruitful spot that lies between long tracts of desert, where the ancient water-courses of the incas, measuring 4 or 5 feet in depth by 3 in width and formed of large blocks of uncemented masonry, are conducted from an unknown distance.
>
> The greatest care was taken that every occupant of the land through which these streams passed should enjoy the benefit of them. The quantity of water allotted to each was prescribed by law, and the royal overseers superintended the distribution, and saw that it was faithfully applied to the irrigation of the ground. (Prescott's Conquest of Peru, Vol. I, pp. 131-133.)

Patches of these prehistoric works are still to be found in the provinces of Mendoza, San Juan, and the upper Andine provinces of the Argentine Republic, though the ravages of time and the reckless indifference of the first conquerors of the country have in nearly every instance reduced them to ruins.

IRRIGATION AFTER THE CONQUEST.

If, however, the early Spanish colonists were more intent in their search for gold than in that for the riches which agriculture produces, their descendants in those far Andine provinces slowly awakened to the fact that the only return they would ever be able to get for their labor would be from the cultivation of the soil. While throughout the pampas, consisting of the provinces of Buenos Ayres, Santa Fé, and Entre Rios, the people followed the lazy but lucrative employment of breeding cattle to the entire neglect or abandonment of agriculture, which exacted more hard labor and patience than they were inclined to give it, in the far interior provinces, where, owing to the lack of seasonable rains, there was a general absence of pasturage and cattle were unable to feed themselves, the colonists were compelled from necessity to direct themselves to agriculture, but they did it in such a way that compared with the science displayed by the aborigines the cultivation of the soil actually retrograded. Mr. Nap, in his work on the Argentine Republic, says:

> While the country was a Spanish colony, agriculture was neglected to the greatest degree, even in those districts where it had previously been the principal occupation of the primitive inhabitants.
>
> Indeed the conquistadores of the Argentine Republic found there an indigenous population more numerous than themselves, which, if it was not quite so far advanced in agriculture as the ancient inhabitants of Peru, had adopted many of their ways and usages in regard to irrigation, and were especially experienced in the cultivation of the soil. The Spaniards, failing in their search for gold, were compelled to accommodate themselves to the circumstances which surrounded them. Thus they adopted the customs and habits of life of the natives, and partially undertook agriculture; and though it was not vigorously exploited, yet it became of a certain importance.
>
> Thus, when the towns increased and a greater consumption was required, the pampa provinces were provided with cereals from the provinces of the interior. For example, the far distant province of San Juan, as late as the year 1860, still sent flour to the Atlantic coast; and notwithstanding the high cost of the transportation by land it was yet able to compete with that of North America, and even surpass it in quality.
>
> But owing to droughts and the constant want of timely rains, it was absolutely necessary to secure the necessary moisture by the artificial means of irrigation; and yet it is unfortunately the case that in some of those provinces so little attention was paid to the proper systems of irrigation that these means for watering the fields were actually worse under the Spanish dominion than they were before the period of the conquest.

Since the organization of the Argentine Republic as an independent government, while agriculture was scarcely thought of in the pampa provinces until recent years, the cultivation of the soil has continued to be the principal occupation of the inhabitants of the interior provinces. And it is only in those of Mendoza, San Juan, Catamarca, Santiago del Estero, Tucuman, Salta, and Jujing that any attention is at all paid to the subject of irrigation. Indeed, but for such artificial means, owing to the lack of rains, it would be impossible to raise crops at all in any of them.

CLIMATE AND RAIN-FALLS OF THE INTERIOR PROVINCES.

In regard to the character of the climate it will be borne in mind that the Argentine Republic extends from 56 to 20 degrees south latitude, and consequently in such a wide zone is subject to a very great variety of climatic conditions. While the far northern provinces have quite a tropical temperature, and the Cuyo provinces have a temperate climate, those portions of the country which extend towards the Straits of Magellan have about six months of quite severe winter. I may also add that the mountain ranges gradually rising on the west to the regions of perpetual snow have great effects upon the temperature even in regions of the same latitude. On this account, in compliance with the instructions of your circular, I shall have to give the character of the climate and the quantity of rain-fall for the different interior provinces separately, beginning with—

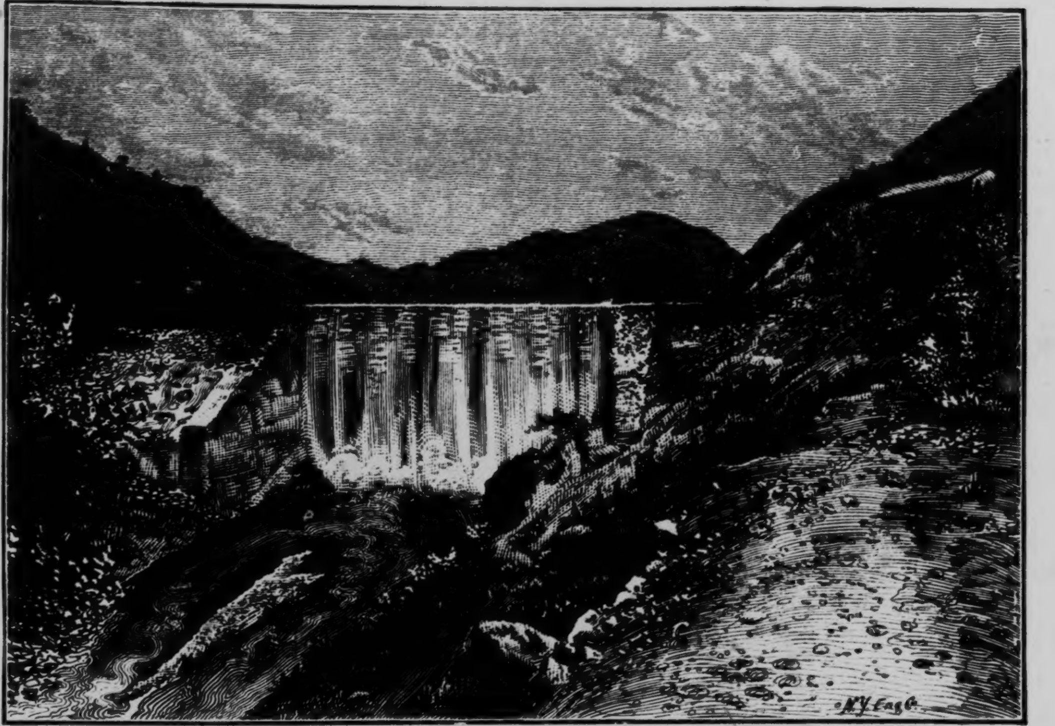
Mendoza.—This province is bounded on the west by the line dividing Chili from the Argentine Republic, and contains about 155,745 square kilometers. A large portion of it is without population. The cultivated portions are mostly in the neighborhood of Mendoza, its only city, which is in latitude 32° 55′ and longitude 68° 49′, and stands at an altitude of 799 meters above the sea. It is situated in the foothills of the Andes. The meteorological office reports for the year 1886 the mean monthly temperature (centigrade thermometer) as follows:

	°		°
January	23.21	July	7.85
February	22.83	August	9.79
March	20.02	September	12.87
April	15.18	October	17.04
May	10.55	November	20.99
June	7.63	December	23.65

The mean temperature was 15.99°. The lowest temperature was 7.5° below zero on the 8th of August, and the highest 41.5° above on the 12th of December, a variation of 49°.

In regard to the rain-fall we have returns of the years 1877, 1878, 1879, and 1880, as follows:

Month.	1877.	1878.	1879.	1880.
January	10.0	0.0	0.3	0.5
February	5.5	11.0	3.3	0.0
March	0.4	7.0	97.0	28.2
April	18.5	2.0	5.0	0.0
May	0.0	8.0	0.0	0.0
June	0.0	0.0	14.0	7.5
July	0.2	[illegible]	0.0	0.0
August	0.0	9.0	10.0	0.0
September	0.1	15.0	2.0	17.0
October	0.0	3.0	65.5	21.0
November	57.5	10.0	8.0	0.4
December	0.0	0.0	7.5	41.0



I.—GRAND DIKE FOR HOLDING THE WATERS OF RIO PRIMERO IN THE VALLEY OF SAN ROQUE, PROVINCE OF CORDOBA.

The director of the meteorological office says:

> From these figures will be understood the extreme aridity of the climate contiguous to the foot-hills of the Andes and that the entire agricultural richness of the Andine provinces depends directly upon the melting of the snows on the elevated peaks of the great Cordilleras. In the city, also, snow is accustomed to fall frequently during the winter, but to no great depth. And yet, owing to the extensive system of irrigation, the greatest part of the lands in the neighborhood of the rivers has been made very productive, being devoted principally to the cultivation of alfalfa, wheat, maize, and the vine.

San Juan.—The province of San Juan lies to the north of that of Mendoza and its western boundary separates it also from Chili. Its mountainous features, however, are more pronounced than those of Mendoza, the Sierras there rising one behind the other in longitudinal chains which form the system of the Andes. The city of San Juan lies in latitude 31° 32′ and longitude 68° 35′, and it is 652 meters above the level of the sea. Twelve years of observations complete gives the mean monthly temperature of the city as follows:

	°		°
January	26.43	July	10.17
February	25.40	August	13.30
March	23.41	September	16.25
April	17.74	October	20.00
May	13.43	November	23.64
June	9.68	December	26.12

The mean temperature is 18.80°. The place is subject to very sudden changes of temperature, the varation in the summer months being sometimes as great as 25 degrees in a few hours.

I have returns complete of the rain-fall for the years 1881, 1882, 1883, and 1888, as follows:

Month.	1881.	1882.	1883.	1888.
January	35.0	3.0	30.0	40.5
February	55.0	12.0	12.0	16.0
March	0.0	0.0	1.0	8.0
April	0.0	0.0	0.0	0.0
May	0.0	6.0	1.0	0.0
June	0.0	4.0	0.0	0.0
July	1.5	0.0	1.0	0.0
August	15.5	0.0	0.0	0.2
September	0.0	0.0	0.0	0.0
October	0.0	7.0	6.0	8.0
November	26.0	0.0	0.0	2.0
December	14.0	0.0	23.0	16.0

It will be seen from these figures that the climate is excessively dry. The clearness of the atmosphere, however, is phenomenal, and although in summer the midday heat is very severely felt, the nights are refreshed by a cool breeze from the south. The "zonda," as the northeast wind is called, is the sirocco of South America, and prevails during the months of July, August, and September, generally beginning about 8 o'clock in the morning and continuing until sundown, during which time the heat is almost suffocating and the air is a cloud of dust. The "zonda," however, is always followed by a south wind, which at once causes a sudden fall of the temperature and re-establishes the atmospheric equilibrium.

In reference to the climate the director of the meteorological office says:

> The quantity of water which falls is entirely inadequate to the requirements of life; and thus it is not astonishing that great tracts of country (travesias) are found almost entirely without vegetation unless the required moisture is supplied by irrigation. With even a limited irrigation, however, these deserts are transformed into fertile fields, which by the contrast seem, as it were, like islands of Paradise, where grow luxuriantly all the products of the temperate zone. The few rain-storms which occur are accompanied by violent winds and great electrical discharges, and hail frequently falls in the months of October and November, causing at times great destruction to the crops.

CATAMARCA.—The province of Catamarca is bounded on the west by Chili and on the north by Bolivia and the Province of Salta. Its superficial extent is placed at 242,309 square kilometers. Its great industry is mining, though considerable attention is also given to agriculture and the dairy. The city of Catamarca is in latitude 28° 25′ and longitude 65° 55′, and its altitude is 545 meters above the sea-level. It is situated in a small valley which on the south opens into a level arid plain. The climate is very similar to that of San Juan, very hot in summer and temperate in winter. The "zonda" here is very frequent and sometimes blows for forty-eight hours, in its progress frequently parching and blasting all vegetation. Indeed the climate is so dry that the drought sometimes continues for eight or nine months of the year. Only on such spots as are moistened by irrigation is any abundant vegetation to be found. The mean temperature for each month is given as follows:

	°		°
January	28.27	July	11.78
February	26.60	August	16.03
March	25.18	September	19.53
April	18.77	October	23.70
May	15.80	November	25.76
June	10.72	December	27.64

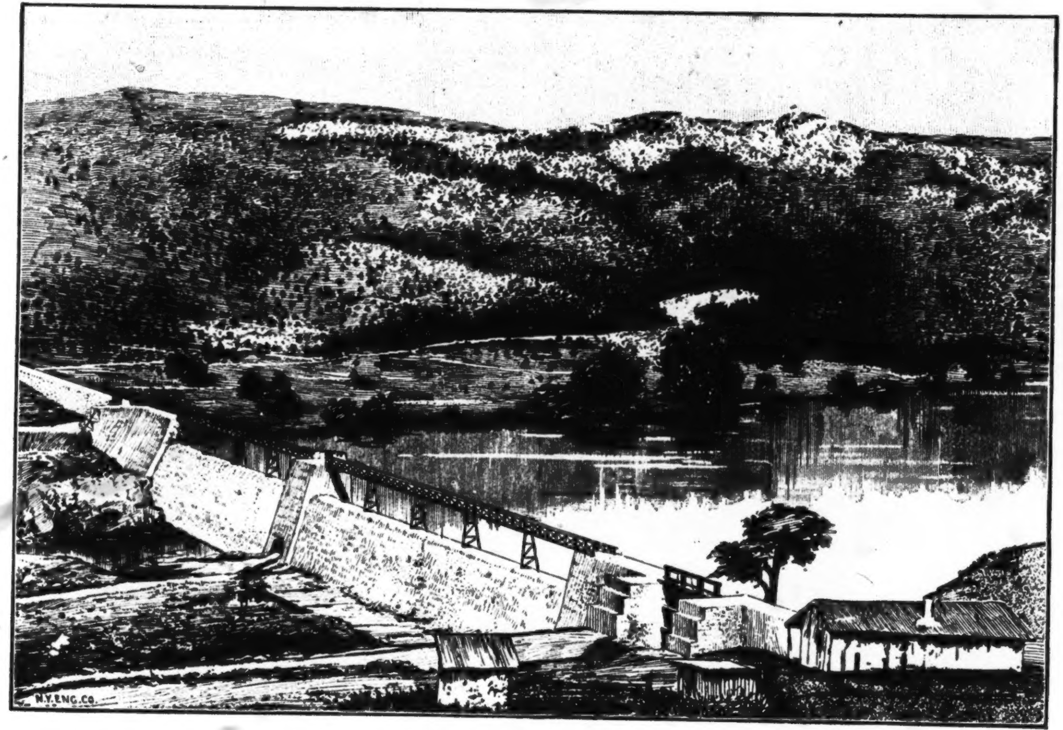
The temperature frequently rises above 40 degrees and scarcely ever known to fall to freezing-point.

I am not able to give the rain-fall, but it is much less than that of San Juan.

TUCUMAN.—The province of Tucuman is to the southeast of Catamarca, but in climate presents a very notable contrast to it, on account of its great humidity and consequently the tropical character of the vegetation. Indeed, owing to its innumerable farms and rich vegetation, it is called the "garden" of the Republic. Its superficial area is about 70,000 square kilometers, a large portion of which is relatively well cultivated the capital city of the same name is in latitude 26° 50′ longitude 65° 12′, and its altitude is 464 meters above the sea. I have the mean monthly temperature of Tucuman for sixteen years, and there is but little variation in the readings. I give that for 1885:

	°		°
January	25.0	July	11.3
February	23.1	August	15.1
March	21.0	September	19.3
April	17.4	October	20.1
May	13.6	November	24.5
June	11.9	December	24.5

The highest temperature recorded was December 25, 1862, when it went to 40 and on three occasions it went down to 0.9.



Report on Irrigation. II.—DIKE OF DISTRIBUTION IN MAL PASO (COMPLETED), IN THE PROVINCE OF CORDOBA.

The rain-fall for the years 1886, 1887 and 1888 was as follows:

Month.	1886.	1887.	1888.
January	307.6	328.0	85.9
February	241.2	95.1	48.7
March	201.1	119.6	211.0
April	26.5	30.3	44.4
May	8.0	5.5	12.0
June	21.1	4.9	29.2
July	0.0	31.8	4.5
August	2.3	2.0	1.5
September	5.6	14.2	65.5
October	40.5	100.4	83.6
November	93.1	97.8	168.3
December	115.2	106.0	221.4

The mean monthly rain-fall by seasons for the fifteen years was as follows: Spring, 205.3; summer, 488.2; autumn, 233.6; winter, 31.1.

Cordoba.—The province of Cordoba is partly pampa and partly mountainous, and, exhibiting great diversity in the quality of the soil, is admirably adapted for agricultural pursuits and grazing, the only drawback being a tendency to droughts during the summer months. The city of Cordoba is situated on the banks of the Rio Primero, just on the edge of the great plain which extends to the Atlantic Ocean, the Sierras rising on the west to a height of 2,500 feet. I have the mean monthly temperature for the last fifteen years, and there is a remarkable uniformity in the figures. I give the following for the year 1887:

	°		°
January	23.4	July	10.5
February	22.4	August	16.0
March	21.0	September	15.5
April	16.3	October	17.7
May	12.7	November	19.7
June	12.7	December	21.6

The rain-fall likewise shows a remarkable uniformity. I have the returns for the last fifteen years, and the largest amount in any one year was 988.7 millimeters, in 1878, and the smallest amount was 528.7, in 1887. For the years 1887 and 1888 it was as follows:

Month.	1887.	1888.
January	91.4	15.3
February	47.8	66.5
March	30.4	130.1
April	68.4	0.0
May	10.5	67.0
June	0.0	2.3
July	7 0	0.0
August	0.0	0.0
September	3.0	9.5
October	49.0	31.6
November	136.3	119 5
December	84.9	161.9

The mean monthly rain-fall by seasons for the last eight years was as follows: Spring, 194.3; summer, 310.6; autumn, 144.3; winter, 16.1.

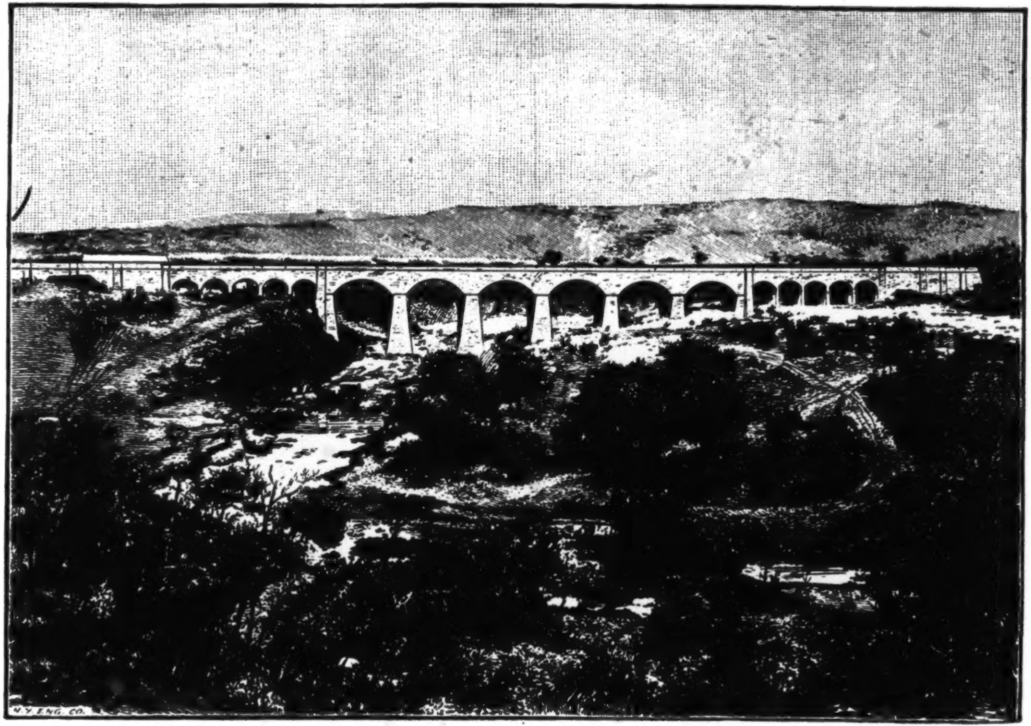
I might extend these meteorological returns, but they are quite sufficient to show the character of the climate in the irrigated regions, and the annual amounts of rain-fall. From an examination of them it will readily be understood that without some artificial means of watering the soil there would not be moisture sufficient for the production of crops with any certainty, unless, perhaps, in Tucuman and Cordoba.

SOURCES OF THE WATER SUPPLY.

The water supply in all these provinces for the purposes of irrigation is almost exclusively from rivers, streams, springs, and small water courses, coming down from the mountains. The great trouble, however, with those rivers which have their sources in the Cordilleras of the Andes is their unequal volume of water. With the melting of the snows, or during the rainy season, they are generally full to overflowing; but they soon run out and at the very times when their waters are most needed. Indeed, with the exception of the system of rivers which flow to the Rio de la Plate and which includes the Uruguay, the Parana, the Paraguay, the Pilcomayo, the Vermijo, and the Salado, there is not a single river in the entire Republic, until we come to the rivers south of the province of Buenos Ayres, which has any outlet. Those of the central system, most of which cross the province of Cordoba, after a dreary course to the eastward, are swallowed up in sands before they reach the Parana. Those which compose the system of the Cordilleras are all lost in quagmires and marshy lagunas before they reach the ocean. With their shallow beds running down very slight inclines, and their great evaporation from the high temperature of summer, many of them quite dry up during four or five months of the year, and these streams are all in those belts of country which have the greatest need of moisture.

CHARACTER OF THE IRRIGATION WORKS.

In regard to the character of the works used for the storage and distribution of the water, as a general thing, it may be said that they are of the most primitive kind. In most cases they consist merely in holding the waters by means of dams built at intervals along the courses of the streams and from the higher levels thus obtained, making canals or aqueducts through which the water is allowed to pass by a gradual descent as it is needed to the lands which are to be irrigated. From these canals the water is distributed by means of sluices and gateways along a system of drains, trenches, or conduits to the fields and meadows which compose the irrigation district. Where the surface is level or flat it is frequently necessary to form artificial slopes for the water to pass over. The whole of the ground is then laid in broad, undulating beds, the upper part of which is quite level from end to end, where the supply channel is cut. All the supply furrows are fed by a main channel at right angles to the beds and somewhat above them. When the flood-gates are opened the water flows into all the upper channels very regularly and evenly till it fills them to overflowing in their entire length. In the case of those streams which come down from the heights of the Andes and course through the valleys or cañons of the Sierras there is no difficulty in holding the water at a higher level than the lands to be irrigated, but where the sluggish rivers meander across an almost level plain, there is occasion sometimes for engineering and the taking of levels. In some instances a channel receiving the water at a higher point than that to which the river flows is dug at a less declivity than that of the bed of the stream and made to carry the water higher than the banks of the river, from which level it is allowed to descend slowly and irrigate the intervening district. In some parts of the Cuyo provinces the works which serve as reservoirs for retaining the waters are of solid masonry, and large sums of money have been spent in their construction. In other provinces the works are merely wooden barriers



III.—AQUEDUCT OF SALDAN OF THE NORTHERN CANAL OF THE IRRIGATION WORKS OF THE RIO PRIMERO, PROVINCE OF CORDOBA.

or earth embankments, which sometimes in sudden freshets are swept away with great damage, thus leaving the people of the district, until they are repaired, without the means of irrigating their lands. I give below the various sources of the water supply.

JUJUY.—This province, which borders on Bolivia, is irrigated at various points by the waters of the river San Francisco, which, making a semi-circle through the southern valleys, finally empties into the Rio Vemejo. While it is the only considerable stream in the province, there are a large number of small mountain riverlets, from which channels also have been dug, and which greatly assist the necessities of agriculture.

SALTA.—On the other hand, this province is supplied with water for irrigating purposes from no less than three large rivers, the Juramento, the San Francisco, and the Vermijo, and by a large number of mountain streams, which are throughout their length utilized for agricultural purposes.

TUCUMAN.—Owing to the chains of mountains which longitudinally pass through the western portions of Tucuman, this province likewise is quite well supplied with water for irrigation purposes; on the south, the streams from the heights of the Aconquija range, from the river San Francisco, and on the east the river Sali, afterwards called the Dulce. These two rivers, together with an innumerable number of mountain riverlets, furnish an abundance of water for irrigation purposes, and nearly all the farms and sugar plantations are thus supplied through the means of ordinary conduits.

SANTIAGO DEL ESTERO.—In this province, the principal source of the waters for irrigating purposes is the river Juramento, afterwards called Salado, which flows along the northern and eastern borders. As far as Sepulturas the river is well banked and both sides are covered with fine farms and sugar plantations, the artificial watering which they receive from the stream producing a marvelous fertility in lands which otherwise would be perfectly barren. Beyond that point, however, it spreads out into marshes or esteros (whence the name of the province) over a country which is unfit for cultivation. Another considerable water course is the river Dulce, which, after leaving Tucuman, flows diagonally through the province, passing by the city of Santiago. In that vicinity it is well banked, and by means of a series of canals furnishes an abundance of water to the estancias and sugar farms on each side. Afterwards, turning to the southeast, it reaches the Salinas or great salt desert, where no vegetation can exist. Beyond this its several channels unite again and forms what is called the Saladillo. Along this stream are to be found spots or "oases in the desert" which have been redeemed by means of irrigating canals, thence coursing over a barren plain the river finally loses itself in an immense salt swamp called Los Porongos.

CATAMARCA.—This has no large water courses, though it is crossed by several small rivers, of which the principal are Santa Maria, the Paelen, and the Piedra Blanca, the two last named forming the Rio del Valle, on which the city of Catamarca is located. These streams and their affluents, and indeed every gorge and valley in the province down which courses a mountain torrent, are utilized ere they are swallowed up in the sands, for the purposes of irrigation. But even then the water supply is so inadequate, that there are throughout the province immense districts without water courses and without rain, which must continue to be little less than sterile deserts.

RIOJA.—Its only river of importance is the Vermijo, and this waters only a very small portion of its surface. This river, coming down from the eternal snows of Mount Boneti, traverses the fruitful valley of Jaque, is increased by the torrents which come from the Valle-Hermoso, and turning its course to the south to receive the surplus waters of the valley of Jacal, finally in latitude 32 degrees loses itself in the sand before reaching the lagunas of Guanacache. Throughout its course it affords excellent facilities by means of sluices for irrigation, but the volume of water is wholly insufficient to meet the requirements of the people, and during the summer months, for want of moisture, there are but few places which escape the wide-spread drought. Wherever there is a thread of water, however, coming down from the Sierras, it has been utilized for irrigation, and in the last few years the Government has been boring artesian wells in the hope of obtaining a better supply of water, but thus far with very little success.

SAN LUIZ.—This province is as poorly supplied with water as Rioja. The only river of any importance is the Rio Quinto, which comes down from the mountains in a series of cascades, and after a southeast course is finally lost in the pampa, in latitude 34 degrees, in an immense salt-marsh called Juncal. There are several small streams whose waters are also, by means of dams and canals, utilized for the purposes of irrigation, but the great want in this province is more water; for although in good seasons there is rain-fall enough for the crops, yet this can not be depended on, and an adequate harvest is only certain in those parts where they have streams for irrigation.

SAN JUAN.—This province is in the midst of the rivers which compose the water system of the Cordilleras. The most northward of these is the Colorado, which is fed by several affluents from the far western Sierras. The second is the Vermejo Chico, which also is formed by several affluents in the snow-covered peaks of Copiapo, at whose foot are a series of magnificent farming districts, all watered by canals from these mountain streams. This river afterwards, turning to the south as I have said, makes its way towards the Laguna Guanacache, but is lost before it gets there. The third and most important of the group is the river San Juan, which has its source in the summits of the Cordilleras, in two affluents, and flowing to the east, down the valley of Pismento, cuts through the mountains and, after passing by the city of San Juan, turns to the south and empties into Lake Guanacache. Formerly, on the breaking up of the snows, the floods which came down this river caused most destructive inundations in the vicinity of the city, and sometimes devastated leagues upon leagues of the most cultivated parts of the valley. To guard against this, an immense dyke has been constructed which acts as a reservoir for holding the water during the summer months. From this reservoir have been constructed numberless distributing canals and conduits all along that beautiful valley; and the water is now so abundant that there is sufficient for steady streams along the gutters of the city. The San Juan all along its course, however, offers marvelous facilities for irrigation. At Murallon, its altitude is 800 meters, while at Lake Guanacache its altitude is only 600 meters, thus giving a fall of 200 meters in a distance of not over 40 miles in a straight line. The river, however, is wonderfully crooked, and affords water for an unlimited number of canals and conduits for fertilizing all the adjacent country. Besides this all the small streams and rivulets which find their way down from the mountains are utilized for watering the lands along which they course—indeed they are entirely absorbed for agricultural purposes.

Report on Irrigation.

MENDOZA.—The system of canals and conduits for irrigation purposes is probably more complete in Mendoza than in any other of the Cuyo provinces, and the absolute requirement of water for agricultural purposes gives its rivers and water-courses a peculiar importance. The most considerable of these is the Rio Mendoza, which is formed by two short branches in the eastern slopes of the Andes, the northern confluent descending from Mount Aconcagua, under the name of Rio Las Cuevas, while the southern, under the name of Rio los Horcones, receives its waters from the peaks of Tupungato. After the junction the river runs to the south through the valley between the Cordilleras, and the Sierra Uspillata, and reaching the level plain near Lujan, shortly afterwards doubles towards the north, in this way arriving at the Lake Guanacache, into which, like the Rio San Juan, it finally disappears. Throughout nearly its entire course, it furnishes the waters for an immense amount of irrigation, while the complicated net-work of channels in the immediate vicinity of the city, with their elaborate ramifications, is one of the great attractions of the place. Heretofore the waters, brought down and through the city in open trenches, was used indiscriminately, also, for drinking and culinary purposes, but two years ago, when the cholera visited this country, the epidemic was peculiarly malignant in that city, owing as the analysis proved, to the bad condition of the water in the canals. Since then, all water used in the city has been brought to it in closed pipes and is separate and distinct from that employed for purposes of irrigation; and the well-known healthfulness of Mendoza has once more been assured.

CORDOBA.—This province has probably greater facilities for extended works of irrigation than any other of the interior provinces, as it is crossed by not less than five considerable rivers, the Primero, the Segundo, the Tercero, the Cuarto, and the Quinto, all of which take their rise in different parts of the Sierras, which range on the western boundary of that province and flow to the east or southeast towards the river Parana, but which only the last named finally reaches, allthe rest losing themselves in the sands of the pampa before they get there. These rivers are all utilized for irrigating the different portions of the province, as are also a number of still smaller rivers, which, rising in the Sierras of Cordoba, have their course towards the west until they finally also disappear in the sands.

With a view to increasing the agricultural facilities of the province and thus inducing immigration, five or six years ago, under the instigation of Dr. Juarez Celman, of that province, now president of the Argentine Republic, there was initiated a series of very extended works of artificial irrigation, the several rivers which run through its territory offering peculiar advantages for the purpose. Surveys and scientific inquiries to this end were made by corps of skillful engineers. The first of these works, under the name of the "Irrigation works of the heights of Cordoba" (Obras de riego de los altos de Cordoba) comprehended the distribution of the waters of the Rio Primero, which passes through the city of Cordoba. The work was commenced two years ago and it is just now contemplated and with most satisfactory results. The entire cost was $3,800,000. It is divided into four parts as follows:

(1) The dike of San Roque. This is a reservoir for holding the water of the river. It is located in a narrow cañon, with precipitous mountains on each side, at a short distance from the confluence of the rivers San Roque and Cosquin, which together form the Rio Primero. It is 51 meters in height and 37 meters from the water-line. The thickness of the wall is 51 meters at the base, laid in cement; 29

meters at the water-line and 5 meters at the top. Its length at the base, being from bank to bank, is 30 meters, and at the top 135 meters. It contains 50,000 cubic meters of masonry. It holds 260,000,000 cubic meters of water and converts the valley into a large and beautiful artificial lake. It contains two flood-gates, a pipe of discharge, and contrivances for removing the accumulations of sand. Upon leaving this immense reservoir, the water flows down the channel of the river until it reaches a spot called Mal Paso, a short distance from La Colera, where a second dike has been built.

(2) The dike of Mal Paso, which forms a reservoir for the distribution of the water. This dike is 10 meters in height and 230 meters in length, from bank to bank, and consists of 13,000 cubic meters of masonry. From this reservoir have been constructed two distributing canals, one of which carries the water to the table-lands on the north, and the other to those on the south side of the river.

(3) Main northern canal. This canal is 25 kilometers long and has eleven acqeducts, one of which, that of Saldan, for its extent, its solidity, and its elegance attracts general attention. The point of distribution is at a height of 37.25 meters above the threshold of the door of the National Observatory in Cordoba. The slope or declivity varies between 0.02 and 0.03 per 100 meters. It has twenty secondary canals. The amount of masonry employed in the construction is 44,000 cubic meters; the excavations of stone and earth reached to 615,000 cubic meters.

Main southern canal. This canal is 37½ kilometers in length, and has twenty aqueducts. The point of distribution is in a plain, even higher than that of the Northern Canal. The slope is the same. It has 89 kilometers of secondary canals. The amount of masonry employed in the construction is 45,000 cubic meters. The earth and stone excavations amounted to 842,000 cubic meters.

The area, which these colossal works will irrigate, amounts to 48,000 hectares at twelve floodings per year; and double that number at 6 per year.

Besides these, the surveys have been completed and approved for similar works on the Rio Segundo, which will hold 350,000,000 cubic meters of water and irrigate 60,000 hectares of land, at a cost of $4,500,000; also for works on the Rio Tercero, whose principal dyke will be 42 meters high and contain 286,000 cubic meters of water, at a cost of $3,850,000; also for works on the Rio Cuatio for which two dykes are to be constructed each 16 meters in height, which will hold 32,600,000 cubic meters of water and irrigate 17,500 hectares of land; also for the Rio de los Sances, which at a cost of $1,400,000 will irrigate 23,760 hectares of land.

The entire cost of the works completed and the works projected is estimated to be not less than $15,280,000 with a capacity to irrigate 1,209,250 hectares of land, which is equivalent to $73 per hectare. If all these works are ever completed the territory of Cordoba, which now in some parts, owing to the want of rain, is a desert, will take a new departure as an agricultural province.

I regret that I have not been able to be more explicit or go into greater detail in regard to the character of the works of irrigation in all the different provinces; but I have found it almost impossible to obtain any authentic information whatever. Upon the receipt of the circular of the Department, I at once applied to the interior department of the Argentine Government, in the hope that it could furnish me with printed reports, surveys or statistics in regard to the more important irrigation or storage systems employed in the interior provinces, but I

TERRITORY WHICH REQUIRES IRRIGATION.

Report on Irrigation.

was informed that it had nothing of the kind at its command. I then immediately addressed letters to the governors, stating the object I had in view and asking for such data on the subject as I supposed of course they would be able to send me; but although over a month has elapsed I have not yet received a word from any of them, and it is hardly worth while for me to delay my report any longer in the hope of obtaining them. Under these circumstances I have had to depend solely on such outside information as I have been able to procure, and except in the case of the works in the province of Cordoba, to speak only in a general way. In regard to the latter I have had access to a book descriptive of the province by Señor Santiago J. Albarracin, and which devotes a few pages to the subject of irrigation. In regard to the other provinces, however, the modes of irrigation employed are generally so primitive and so simple, being in most cases mere trenches with sloping slides, that I doubt if it would be of any service, even if I could give more detailed statements in regard to them.

DISTRIBUTION OF THE WATER.

In regard to the rules or laws which govern the distribution of the water, of course it all depends upon the tenure of ownership. In many of the provinces, if not indeed in all of them, there are numerous canals cut for irrigating purposes which are the property of the owners of the land, through or over which the canals are made. The province has had nothing to do with their construction and of course collect no rental or tax for the water used. Where the works have been constructed by the provincial governments a tax is paid by those who make use of the water, and this varies in the different provinces according to the expense or cost of the works. I regret that only in a few cases I am able to give the rates charged for the use of public water, not having been able to procure the laws under which the irrigating canals have been constructed.

In the province of Santiago des Estero, it is provided that all agricultural establishments and gardens which use the water of the public irrigating canals shall pay a tax of $1.50 per hour; and manufacturing establishments shall pay $2 each time they request the water, not to exceed four hours each time; for a single hour 50 cents each time. Subscribers for the use of the water for irrigation have the right to six times per month during the year; and in case they do not receive this amount in the course of the year, they are entitled to a proportionate rebate, but the law does not appear to state what amount of water shall be used.

In the province of Mendoza the annual tax is $30 per square (about 5 acres), the water to be used not oftener than one day in the week, the tax to be paid quarterly. For each house situated on the canals, where there is a service of water, a tax of 25 cents per month is charged. Those who make use of the water surreptitiously, or who use it out of their turns, must pay a fine of $20 for each offense.

In the province of Tucuman the water of the "Western Canal" is sold for the purpose of irrigation at the rate of $3 per mark per twenty-four hours; and for brick making at 30 cents per 1,000 bricks.

In Catamarca 6 cents per hour is charged for the use of the water from the Rio Tala, payable monthly.

In Cordoba the charge per square is $30 per year, payable quarterly, the water to be used one day in the week. Those who use the water out of their turn or without permission are liable to a fine of $20 each time

WATER RIGHTS BY PRESCRIPTION.

These water-rates, however, it will be borne in mind, are only collected in cases where the provinces are the proprietors of the works. In many cases, as I have said, the canals are the property of the land owners on each side of the stream. It is a part of the history of the conquest that when the Andine regions came into the possession of the Spaniards they occupied the country in the neighborhood of the rivers in some cases, driving the original inhabitants away from their settlements; and in others not only appropriating their settlements, but even reducing the Indians to the condition of slaves and requiring them to cultivate lands which were their own. These lands were held in vast estates, and with the organization of the governments it was found that all the arable places were in the possession of comparatively a few persons, who either found irrigating canals already constructed upon the lands or who compelled the enslaved Indians to dig them. Thus all these landed estates have had from the beginning a right to the use, if not the control, of the streams along which they are located. And, as with the increase of population, these estates have gradually been divided up into smaller properties and sold; a certain amount of the water for irrigating purposes have been sold with them. Thus the quantity of water which the different properties are entitled to is in most cases fixed by their title deeds.

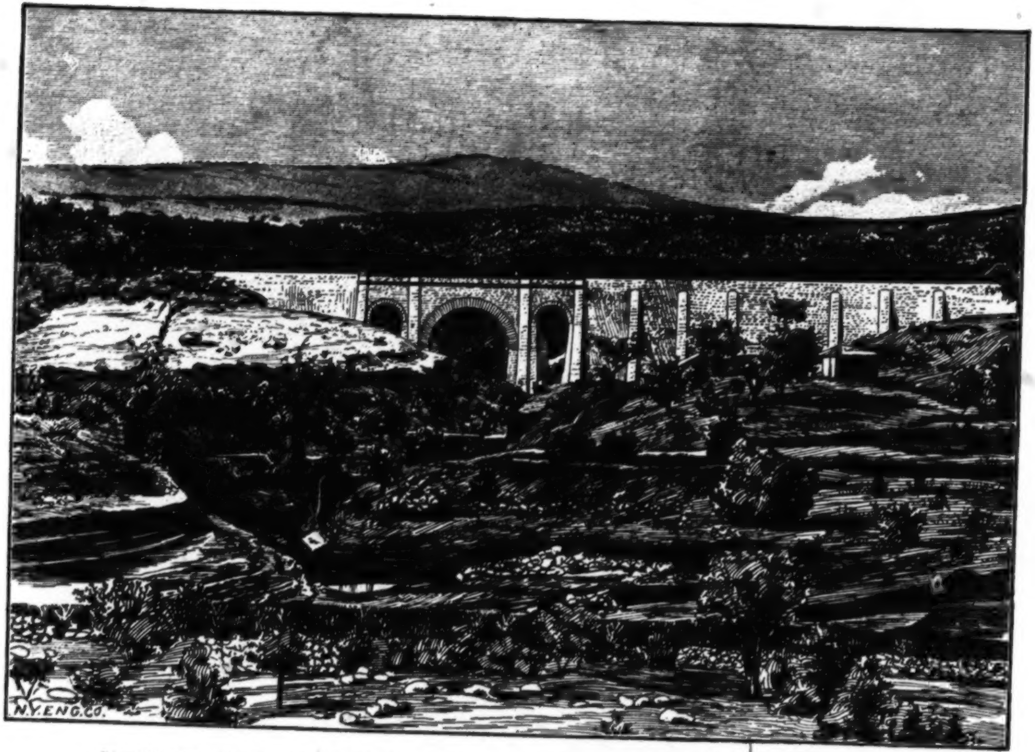
AREAS OF LAND UNDER IRRIGATION.

In regard to the areas of land under irrigation, compared with such as are cultivated without irrigation, together with the quantity and quality of the crops grown, it is not possible to speak with exactness. As no census of the country has been taken for the last twenty years it is usual to base all calculations on estimated figures, and that is all that can be done in this case. Fortunately I find in the message of the President of the Republic to the present Argentine Congress a table of statistics, "being the first ever attempted," giving the amount of land under cultivation in each province for the year 1888, compared with the total areas. I reproduce his figures below:

Provinces which depend on irrigation.

Provinces.	In cultivation.	Total area.
	Hectares.	*Hectares.*
Cordoba	234,395	17,476,700
San Luis	19,809	7,591,700
Mendoza	88,540	16,081,300
San Juan	79,630	9,750,500
Rioja	22,817	8,903,000
Catamarca	44,618	9,064,400
Santiago del Estero	120,400	10,235,500
Tucuman	35,943	2,419,900
Salta	38,525	12,826,600
Jujuy	18,904	4,528,600
Total	703,077	98,878,200

Thus, out of a total area of 98,878,200 hectares of land in these interior provinces, we find that only 703,077 hectares are under cultivation, being scarcely .07 per cent. of the entire area. It will readily be seen from this that it is only along the water courses that there is any irrigation, or indeed any vegetation at all.



IV.—AQUEDUCT No. 13, NORTHERN CANAL OF THE IRRIGATION WORKS OF THE PROVINCE OF CORDOBA.

Report on Irrigation.

The provinces which, owing to the frequency of the rains, do not require irrigation for the production of crops, are the following:

Provinces which have no irrigation.

Provinces.	In cultivation.	Total area.
	Hectares.	*Hectares.*
Buenos Ayres	868,658	31,123,700
Santa Fé	586,537	13,158,200
Entro Rios	136,151	7,545,700
Corrientes	46,631	8,114,800
Total	1,637,977	59,942,400

In these four riverine provinces out of a total area of 59,942,400 hectares of land, there are 1,637,077 hectares under cultivation, being about 2.5 per cent. of the entire area.

The President in his message calls attention to the difference in the percentage of land under crops in the riverine provinces and in the interior provinces, and says: "It shows the relation there is between easy means of communication and the cultivation of the land." There is no doubt that the outlet the formor have to the sea-board does give them some advantage, but the great advantage which they possess consists in their better climate and their more reliable supply of moisture from fertilizing rains. A large percentage of the lands in the interior provinces, owing to the limited supply of water they afford, beyond the immediate banks of their water-courses, must continue to be what it now is, an unproductive area of desert, unless the deficiency can some time be made up by the sinking of artesian wells, a problem which the Argentine National Government has for some time been trying to solve, thus far, however, without any great success. Should artesian water, however, be finally reached in sufficient quantities to meet the requirements of agriculture, all the interior provinces, most of whose areas are now but waste places, would receive a new stimulus and have a more prosperous future in store for them. They would then be able to produce crops not only of as good quality, but perhaps in as great quantities as the more favorable portions of the Republic. Until then, however, the provinces of the littoral must continue to be the chief centers of the Argentine agricultural industry.

PACIFIC OCEAN.

REPORT FROM H. W. SEVERANCE, U. S. CONSUL-GENERAL, HONOLULU, ON IRRIGATION IN THE HAWAIIAN ISLANDS.

This report has been delayed in order to include reference to a published report, now inclosed, on water-supply for irrigation by Messrs. Schuyler and Allard*. Thesee ngineers, being competent men, have examined the sources of supply on the island of Oahu, as well as giving valuable information concerning irrigation on the other larger islands of this group; and although this information is limited, the fact is fully established that irrigation is essential to success in the growth of the leading product, sugar-cane, as well as rice.

The only map bearing upon this subject is attached to the report of Messrs. Schuyler and Allardt. It has been difficult to obtain the information in an extended form but the points to which the circular alludes have as far as possible been answered in this report.

---

* Report not received.

Where irrigation is continuous the product of sugar has increased to an average of 4 tons per acre, while the same lands without irrigation formerly yielded only the average of 2 tons per acre.

The area of good cane land is limited; the most reliable estimates do not exceed 90,000 acres. Of rice land 7,000 acres, and of land suited for bananas at present under cultivation 3,000 acres; total, 100,000 acres. Of the cane land about 45 per cent. is irrigated, the remainder, except for rice land, which is all under irrigation, is subject to the annual rain-fall, which is copious on the high lands on the windward or eastern side, while it is limited on the leeward or western side.

The quantity of sugar produced in the year 1888 was estimated at 120,000 tons. Two-thirds of this of a good light color, polarizing from 86 to 96°, and one-third of the yield polarizing from 76 to 84°, all of which was sold at good figures for refining purposes.

The estimate of rice was 20,000 tons, one-third of which was exported and the remainder consumed here. All of good quality.

Of bananas about 100,000 bunches; 75,000 exported, balance consumed here.

THE SOURCES OF WATER-SUPPLY.

From mountain streams, springs, artesian wells, and storage reservoirs.

THE CHARACTER OF WORKS, DISTRIBUTION, ETC.

These consist of dams and basins, by which water is imponded and then conveyed by wrought-iron and cast-iron pipes, flumes, and open water leads and ditches at various distances from 5 to 40 miles. This system of distribution is regulated largely by leases from land-owners and by custom and common consent with sanction of law.

AMOUNT OF WATER USED PER ACRE AND PER SEASON.

For twelve months' irrigation per acre on the Spreckelsville plantation on Maui 566,280 cubic feet were used, equal to 3 inches per acre, every week, or say 5.8 cubic feet for 1 pound of sugar produced. This may be a large quantity, as the usual estimate would be 1 cubic foot of water per second to properly irrigate 45 to 65 acres of cane or 30 acres of rice.

THE COST OF RENTAL TO USER.

On page 21 of report forwarded the highest cost of pumping is estimated at $3 per acre per month, or $45 per acre per crop. No reliable estimate can be found of cost of water-supply distributed by pipes, ditches, flumes, artesian wells, or springs. This would depend on the distance, the means of conveyance, the character of the country, and the flow.

TENURE OF OWNERSHIP OF WATER.

Both private and by lease from Government.

CHARACTER OF CLIMATE IN IRRIGATED REGION.

Variable, according to elevation; on the leeward or western side, in proximity to the ocean, dry; the eastern side generally moist and cool; good soil in the valleys, yielding fair crops.

ANNUAL RAIN-FALL.

Mean rain-fall on the island of Oahu from 1867 to 1883 was 62.6 inches (see page 24 of report inclosed), while the minimum rain-fall, along the coast exceeds 24 inches, and upon the mountain slopes from 40 to 90 inches, according to elevation; in the Hilo district on Hawaii, 120 inches.

ANTIQUITY OF IRRIGATION SYSTEM.

A system of irrigation has always existed among the Hawaiians throughout the Kingdom, conveying the water from the mountain slopes and springs through the valleys over hill-sides for the production of their chief article of food, the *Arum esculentum* or kalo, from which poi is made. Many of the ancient water leads are still maintained at private expense by the owners of leases of the land running from the mountain to the sea.

ASIA.

REPORT FROM JOHN TYLER CAMPBELL, U. S. CONSUL, FOOCHOW, ON IRRIGATION IN CHINA.

As the rain-fall is equally distributed throughout the year in this province (Fohkien) there is no land dependent alone on irrigation; but in the culture and growth of rice, which is generally understood to be the principal crop grown here, irrigation is at times indispensable, and is a subject which deeply concerns the farmer in this country. The rice crop can not be made without a great deal of water, and in the seasons of drought its absence is sorely felt.

THE CULTIVATION OF RICE.

In the first place a small piece of ground is highly fertilized, plowed, or dug up and put in good order very much as cabbage beds are prepared, then the rice seeds are sown, after which the water is turned on and the bed kept submerged with about a half of a foot of water until the plants are sufficiently large to be transplanted to the fields. And here again irrigation is required. The ground is plowed and put in order for the plants, but before planting the fields are covered with water about one-half of a foot deep and the soil is worked into mud; the plants are then set into the mud and water in rows. Water is kept standing on the land until the plants are well along. Irrigation is therefore essential to rice growing.

HOW LAND IS IRRIGATED.

This country is well situated for the construction of reservoirs on a large scale. Dams could be easily built across the gulches and deep caños in the mountains, and reservoirs could be made wherein immense quantities of water could be stored and when needed for irrigation could be turned on the fields in the valleys below by the force of gravity, but this idea has never been acted upon by the Chinese, if it ever entered their minds. Small ponds are made adjacent to the fields, and the water is pumped from these and the natural water supplies into the rice fields by man power alone.

THE MODE OF IRRIGATION.

The water used for irrigation is drawn up from the ponds and water-courses by an endless chain, or rather an endless rope pump, which is worked by one man or sometimes two men by treading upon a wheel, made with a number of radiating arms, which causes the wheel to turn upon its axis. A horizontal pole about 5 feet above the shaft is made fast, and the men support themselves by leaning upon this pole while treading the wheel. One end of the box through which the chain draws the buckets is placed in the water at an angle of about 45 degrees with the pond, river, or canal from whence the water is drawn into the field. The box is open at both ends and is made strong and light. The whole apparatus is easily carried by one man on his shoulders. The faster the man treads the wheel the more water is pumped, and the machine is kept going night and day when water is needed for irrigation.

The pump is run very much on the principle of the tread-mill so far as the motor-power goes, and the water is carried up with the buckets something like wheat is raised in an elevator. In this province neither horse nor steam power has ever been thought of, and the manner of pumping water it is believed has not changed for three hundred years. Water is conducted into the fields, which are usually marked off into small compartments, according to the number of proprietors, by earth embankments, the water filling one after another until all are covered. Horses are never used in this province by the farmers, and in fact are rarely seen here. Everything is carried by human beings on their backs. The vegetable garden, flowers, and small plants are watered by water carried on the backs of the laboring people—men, women, and children.

None of the modern appliances for conducting water over the land have as yet found their way into China. No greater or stronger power than human hands is ever called into requisition, nor is there any likelihood of any innovation to the long-established custom being permitted in this land where farms are so small and labor so cheap. No farmer will expend money in experiments for irrigation when he can hire a laborer at from $10 to $12 per year to keep the time-honored pump in motion. The working classes themselves would strongly oppose the introduction of labor-saving inventions that would take work from them, and tend to cut off their employment. The farms are small, less than 1 acre in many cases, but they have been tilled for perhaps thousands of years, and by the skillful use of fertilizers and by care and attention to each plant crops are raised that would astonish the owners of rich soil.

THE WATERS OF THE RIVER MIN.

The river Min runs diagonally through this province, and a few miles above this city it divides into several branches, which, after pursuing separate courses for 15 miles, unite a little above the pagoda anchorage, and empty into the Pacific Ocean 2 miles below. Along the river are numerous small valleys which can be easily irrigated from the river, but the mode of irrigation is rude and simple. The pump is used for the larger fields and small plants, and garden vegetables are watered by water carried on the backs of the laboring people. The everlasting pole on the shoulder of the bearer, with buckets suspended from each end, is rarely out of view. The water is carried in this way, in many places a long distance, but no complaint is heard in any quarter. When the rains cease water must be supplied to keep alive the growing vegetation so essential to the existence of the people. During a dry season men, women, and children are engaged in carrying water which is carefully sprinkled over the vegetation, and the greatest patience and care are shown in keeping moisture about the plants. In this part of China the rain-fall is fairly distributed throughout the season, but if the rain does not come at the needed time the water buckets are called into requisition to supply the necessary water for the crops.

LAND UNDER IRRIGATION.

There are no means of ascertaining the area of land grown in rice. This seems to be the only product of the soil that necessitates irrigation. There are no statistics available showing the quantity of land under cultivation. As far as observation goes the whole face of the country, excluding the precipitous mountains and running streams, is used either for farming purposes, for residences, or for cemeteries. The water-supply is abundant for all purposes in ordinary times. There are numerous rivers, streams, and springs in all parts of the province. There are no laws governing the use of water. Custom rules in this as in almost all the affairs of life in China.

REPORT FROM THOMAS F. PETTUS, U. S. CONSUL, NINGPO, CHINA, ON IRRIGATION.

(1) It is impossible to ascertain the areas of lands under irrigation or cultivation, owing to the difficulty in getting at the records kept in the tax office and the absence of published returns of land taxes. The district is well cultivated, and every strip of land available is under cultivation.

(2) The supply of water for bottom land is from canals. The supply canals are run from the river to the hills, dug from 50 to 80 feet wide. At the foot of hills all running water from springs is emptied into the canals, so as to form a never-failing supply of fresh water. The canals are not allowed to connect with the river, as the water in the latter is salt or brackish. At the foot (or end) of the canal an embankment of stone is made to a height above the sides of the river, this is covered with moistened, slippery clay, so that boats entering or leaving the canal are hauled over. A hawser of twisted split bamboo is fastened either to the stern of the boat or a strong beam crossing it at the bows. The hauling is usually done by capstans, sometimes by oxen.

These canals have no locks. The supply canals are from 2 to 4 miles apart; minor canals are dug at right angles, and supplied with water from the main arteries, about 200 to 400 feet apart, from 10 to 30 feet wide. Thus every farm and garden is supplied with free water.

(3) The farmers, when compelled to irrigate their land, use a wooden chain-pump, which is as long as required, placed so as to draw water from the canals, worked by cog-wheels, the ox performing the labor; so a stream of water some 10 inches wide constantly flows. A field of 2 or 3 acres of rice is soon overflowed.

For gardens and small plots of ground a hand-pump of the same kind is used, generally worked by two men.

The hill lands are terraced and are irrigated by springs, water being conveyed by small ditches or by pipes made of bamboo.

(4) There are no laws or rules governing the water system. The canals are free, and there are no expenses to the user beyond those of drawing the water from the canals.

(5) Climate damp and warm from April to 1st of July; July, August, and September, hot and dry; November and December, dry and pleasant; January, February, and March, damp and disagreeable.

The system of irrigation according to Chinese is over a thousand years old.

The soil is alluvial. Rain-fall for 1888 was 68.31 inches.

REPORT FROM CHARLES SEYMOUR, U. S. CONSUL, CANTON, CHINA, ON IRRIGATION.

(1) Irrigation of land is so general in southern China that a comparison between irrigated and non-irrigated lands is impossible. Rice is the chief crop on which cultivators rely for support, but near Canton and other large towns and cities a great diversity of productions may be found, as vegetables of all kinds are cultivated, and the lands being so subdivided as to be devoted to small parcels, and under the management of small owners, to many kinds of crops, with a view to early supplies for immediate city consumption.

The yield of good land,* which has been properly fertilized and irrigated, supports a family of five persons, who will each consume 2 pounds of rice, and other things in moderate variety and supply. Two crops of rice and one of vegetables are produced annually when the land is well tilled. A ton and three-quarters of rice per acre each year is a fine crop. In tilling the small pieces of land about Canton, with a generous use of fertilizers, the utmost vigilance is given to irrigation.

(2 and 3) The sources of water-supply are the small tributaries of the large branches of great streams, and in many places where they are inaccessible pools of water are held in reserve by hardening the bottoms and sides of pits and hollows and depressed or sunken lands. Between rows of growing vegetables, trenches filled with water, obtained from the creeks, brooks, or pools, are kept, and once or twice a day the water is scooped from these trenches upon the raised grounds, in which the roots have great depth of loose and moist soil to promote growth. When these trenches of water are not available, owing to scarcity of water or to porous land, the men and women carry, suspended from a yoke across their shoulders, two large buckets with long spouts, and sprinkle the rows of vegetables copiously. Sometimes the water for this purpose is carried in buckets a considerable distance. For the irrigation of rice lands, which have to be submerged, the lands are divided into small patches at different levels, so that the appearance is that of a beautiful system of terraces, near a bountiful supply of water, which is raised to the upper level by chain-pump and tread mill process with coolie power. From the upper to lower levels the water descends so gradually as to avoid washing away the substance or fertility of upper to lower lands.

(4) The system of water distribution is generally conducted and used on the mutual or co-operative plan, which prevails in China in so many branches of industry and business as to lead one to believe co-operation is reduced to a perfect system on the basis of equity.

(5) The character of the climate in this province is mild and warm. The lowest temperature at Canton in winter is about 37 or 38° Fah. The rainy season of March and April, with copious showers and rains of considerable frequency during May and June, and occasional show-

---

*The consul makes no mention of the area required.

ers up to the end of August, supplying crops with abundant water when most needed for the first and second rice crops. The actual measurement of rain-fall is not known. During the rainy season the water-fall is torrential at times.

The antiquity of the irrigation system in China is established. This portion of China is favored with streams, and water-ways, sloughs, and natural deposits of water for the temporary season of drought; so that being abundance of fertilizing properties available for agricultural and horticultural operations, the excellent supply of water required for irrigation of land favors the production of the largest crops of which any land is capable of yielding.

REPORT FROM A. C. JONES, U. S. CONSUL CHIN KIANG, CHINA, ON IRRIGATION.

SIR: In compliance with the circular letter of instructions of the Department of State, on the subject of irrigation, dated May 2, 1889, and received on the 7th instant, I have the honor to inform you that, so far as I can learn, there never has been any national or other governmental system of water distribution in China. There are no reservoirs worthy of the name in any part of the country. This province of Kiangsie, as its name signifies, is the province of rivers and mulberry trees, and is perhaps the best-watered section in the empire. The almost annual inundations, caused by the overflow of the Yellow River and the Yangtsze Kiang, fertilizes the submerged lowlands of the province and renders unnecessary any artificial means for the cultivation of crops except that of rice, which requires in the early stages of planting and growth a great deal of water.

The methods of providing water for the rice and other crops in general all over the country are very simple, and are governed by no laws or regulations beyond the local customs of the people.

The farms, so-called, are rarely over 2 acres in extent, and are separated by ditches or raised pathways. There are no fences and no ranging stock.

To provide a water-supply for the fields the farmers usually club together and make large pools to receive the rain for common use. It is then when required supplied to the fields by pails. When a natural streamlet exists, it is utilized by conducting it through ditches or bambo pipes to the fields.

Sometimes the water is supplied from the streamlets by the most primitive arrangement of a water-wheel worked by treading with the feet.

These are the methods in vogue since the earliest days in this district, and no improvements on them have ever been attempted. In other districts I have seen the water-wheel worked by buffaloes.

The rain-fall is very uncertain. Usually in May and part of June there are heavy rains; but last year a long-continual drought almost destroyed the whole rice crop of the district.

In reading of the astuteness of the Chinese and of their reputation generally as to shrewdness and sagacity, one naturally would expect other things of them; but my observation of the working class and the farmers leads me to the conclusion that while they are hard-working and patient, they are a shiftless and hand-to-mouth people.

REPORT FROM J. D. KENNEDY, U. S. CONSUL-GENERAL, SHANGHAI, ON IRRIGATION IN CHINA.

Following the Department's inquiries in their order I have to report as follows:

(2) Rice fields are usually flooded from rivers, streams, and canals.

(3) There is no system of storage of water for irrigation.

(4) All irrigation throughout this section of China (if flooding rice fields may be called irrigation) is carried on by individuals. No further information under this heading obtainable.

(5) Warm, moist, and fertile.

(6) The present means of pumping water from streams into fields has been practiced in China from time immemorial.

In general: From Mr. G. James Morrison, an English civil engineer, who has had much experience in China, I learn that from observation made during extensive journeys in the interior of this country he has seen no other means of irrigation than the system of pumping from streams directly into the fields, save the more laborious method he saw in the northern sections of China of lifting water in buckets and throwing it over the bank by hand.

On the island of Formosa he saw a more extensive system of irrigation, the water being conducted down the hills for some distance.

From Mr. John Fryer, a distinguished sinologue, to whom I applied for assistance in making this report, and who obtained his information from Chinese sources, I learn that in northern Shan-Si an arid tract of land has been reclaimed by irrigation. The information is so meager that I merely mention it. In many sections of China there is at the present day extensive tracts of arid land and no attempts are made to reclaim them.

REPORT FROM JACOB I. CHILD, UNITED STATES CONSUL-GENERAL, BANGKOK, ON IRRIGATION IN SIAM.

About one-half of the country is under cultivation, and of this portion fully four-fifths is under irrigation.

Rice is the staple, consisting of two kinds, Va Suan, or garden rice, which is tranplanted, and the second grade, Va Muang, or field rice.

It is estimated that about 10,143,800 piculs are annually grown in Siam.

Water is supplied to the fields by means of canals, which branch out from the rivers in all directions.

The water is conducted into the fields by small canals and ditches (the fields are divided off into ris, containing about one-third of an acre), around the four sides of each ri, in turn, until the whole number of ris is full.

There are no published works upon irrigation. This system is governed by laws and customs. There is no duty upon the water, but if the land is government property there is an annual rental in the form of a tax of 28 cents per ri, which includes the use of the water. The large canals are built at the expense of the general government, but the small canals leading to the fields must be dug by the individual.

The climate is tropical, with a wet and dry season. The average annual rain-fall is 67.04 inches.

The system of irrigation has been in use from time immemorial and is maintained partly by public and partly by private expense.

REPORT OF ERHARD BISSINGER, U. S. CONSUL, BEIRUT, ON IRRIGATION, ETC., IN SYRIA.

(1) AREAS OF LAND UNDER IRRIGATION, ETC.—As there are no statistics kept in Syria it is not possible to state with any degree of positiveness the exact areas of land under irrigation, and the different authorities competent to speak on so important a subject differ somewhat in their various estimates. A high government official in Damascus, who has devoted much study and attention to the matter, gives the approximate area of cultivated land in the vilayet or province of Syria as 30,000 feddans—336,000,000 square feet. (A "feddan" in Syria is understood to comprise that extent of land which can be plowed and prepared for seed by a pair of oxen in one day.)

An equally reliable and competent authority in Beirut, from his own observations and knowledge of the country, estimates that only about 5 per cent. of the cultivated lands are irrigated in the province known as Mount Lebanon, and probably not over 2 per cent. in all Syria, while the proportion of irrigable, as compared with non-irrigable, areas is calculated by the former authority as equal to about three parts out of twenty-four, or 12½ per cent.

Quantity and quality of crops grown.—The total quantity of crops grown is not ascertainable, not even approximately, and any attempt to arrive at exact figures would be useless and a mere waste of time.

The quality of the crops varies according to climate, soil, and locality; they comprise nearly all the cereals grown in the United States, besides "durah" or maize (both yellow and white), sesame, hemp, cotton, etc., also bananas, pomegranates, figs, dates, oranges, lemons, mulberries, olive, and other fruits, and all kinds of vegetables and other garden products.

Orchards well watered, as those for instance at Sidon, Tripoli, and other places in Syria, are reputed to be very remunerative in a pecuniary point of view, yielding, it is said, as high as 10 per cent on the capital invested, clear of all expenses.

(2) *Sources of water supply.*—The sources of water supply are lakes, rivers, streams, and other water-courses, springs, ponds, wells, and cisterns or tanks. The waters of lakes for irrigation purposes are only utilized in a few instances, such as Homs, Tiberias, etc., as will be seen later on, and reservoirs, on a large scale, do not exist at all in Syria.

(3) *Character of works used for storage and distribution of water.*—Published reports of irrigation and storage works do not exist; a wood cut of a huge Persian water-wheel in use at Hamah, with an accompanying description in print published from notes furnished by a competent authority here, is all I have seen.

Generally speaking the character of the irrigation works is of the most primitive kind. From rivers the conveyance of water is usually by means of canals or rough ditches badly leveled and aligned, often without masonry except at the intake, the retaining weirs for obtaining necessary head being remade every season of bowlder, stones, and brush-wood, rarely over 3 feet high.

Irrigation from springs is generally much the same as from the rivers, though necessarily on a smaller scale.

From wells the system universally employed is that of the "Na'hura."

The "Na'hura" is of the simplest construction, cheap, quickly made and repaired, and easily worked, while it raises a comparatively large quantity of water. Its construction consists of a clumsy cog-wheel, fitted to an upright post, and made to revolve horizontally by a donkey, mule, or horse attached to the sweep; this turns a similar one perpendicularly placed at the end of a heavy beam, which has a large wide drum built into it, directly over the mouth of the well.

Over this drum revolve two rough hawsers, or thick ropes, often made of "myrtle" twigs and branches twisted together, and upon them are fastened small earthen jars or wooden buckets. One side descends while the other rises, carrying the small buckets with them; those descending are empty, while the ascending ones are full, and as they pass over the top they discharge into a trough which conveys the water to the cistern. The length of the hawsers and number of buckets depend upon the profundity of the well, for the buckets are fastened to the hawsers about 2 feet apart; the wells are of different depths, but generally average from 10 to 15 feet. It is claimed that with good animal power a bucket containing about 2 gallons of water can be raised every second (see table in "Acca-Haifa" report).

The "Shaduf," so conspicuous on the Nile, is not used in Syria, but on the shores of Lake Tiberias an apparatus much like it has been seen at work, and the well-sweep and bucket is also met with in many places.

Another method (very common in the land of Philistia) may be observed on the plains of central Syria. It is a large buffalo skin so attached to cords that when let down into the well it opens and is instantly filled, and being drawn up, closes up so as to retain the water. The rope by which it is hoisted to the crop works over a wheel and is drawn by donkeys, mules, oxen, or camels that walk directly from the well to the length of the rope and then return, only to repeat the process until a sufficient quantity of water is raised; this is also a very successful mode of drawing water.

The wheel and bucket, of different sorts and sizes, are much used where the water is near the surface, and also along rapid rivers. For shallow wells merely a wheel is used, whose diameter equals the desired elevation of the water. The rim of this wheel is large, hollow, and divided into compartments answering the place of buckets. A hole at the top of each bucket allows it to fill, as that part of the rim, in revolving, dips under the water. This, of course, will be discharged into the trough when the bucket begins to descend, and thus a constant succession of streams falls into the cisterns. The wheel itself may be turned by donkeys, mules, oxen, or camels.

Small water-wheels are sometimes turned by feet, but the process is tedious, toilsome, and not productive of much result.

At Homs, in the Tripoli district, there is a lake or artificial basin of about 4,000 acres in extent, formed by draining the Orontes River. It is very shallow in summer, probably not over 10 or 15 feet at the deepest part, but will reach a depth estimated at from 30 to 40 feet in the winter. The lake was made for the double purpose of regulating the summer flow of the Orontes and for obtaining sufficient head of water to irrigate the extensive gardens of Homs. This lake is the only artificial system of irrigation on a large scale in the country, but it is not kept in very good repair.

The "Pools of Solomon," at Tyre, may also be mentioned; they are natural artesian wells of great volume, irrigating some 1,500 acres of garden land from artificially raised conduits.

(4) *The system of water distribution, etc.*—In regard to this, Ottoman law literally says:

> In contestations relative to water-courses for drinking or irrigating purposes, the customs and usages existing *ab. antiquo* only are to be taken into consideration.

These usages and established rules vary somewhat in different localities; but it is the almost universal custom that the water belongs to the community and to the lands irrigated by it; the allotted quantities of water can not be altered or alienated without the permission of all the proprietors unanimously; nor can the lands be sold without the water, nor the water without the lands.

The amount of water used per acre—is estimated by a reliable authority as varying from 25 tons in the plain for garden products to 4 tons per acre in the high lands for mulberry trees.

The actual or precise quantity of water used per acre or season, can not, however, be accurately stated; it varies greatly according to the soil and its products. Mulberry trees, for instance, need only to be well watered three or four times during the dry season; but the water should penetrate the ground at least 3 feet. This would require the the land to be inundated to a depth of at least 8 to 10 inches. Vegetables, cereals, etc., should be watered more frequently, at least once or twice a week.

Where there is scarcity of water, judicious manuring would do much towards assuring good crops; but this practice, outside of the vicinity of Beirut and other large cities, is either wholly unknown in Syria or only resorted to in very isolated cases.

Tenure of ownership of water, etc.—The Turkish regulations and laws are very comprehensive and precise on this subject, and for a fuller understanding of the same, a translation of the most pertinent paragraphs is appended herewith:

OTTOMAN REGULATIONS CONCERNING PROPRIETARY RIGHTS OF WATER, ETC.

Water, herbs, and fire are things *ex commercium*; all men enjoy them in common.

Water running under ground is the property of no one in particular.

Wells not sunk by any one in particular and which are used by the public in common, are *ex commercium*.

Seas and great lakes are things *ex commercium*.

Streams of the public domains, that is to say, those which do not specially belong to any one, are those whose bed is not the property of a number of persons; such streams are *extra commercium*, as for example, the Nile, the Euphrates, the Danube, etc.

"Private" streams (Arabic, *enharmunlouké*), *i. e.*, those whose beds traverse the lands the property of private persons, are of two kinds.

First. Those whose waters are subdivided among co-proprietors, but which do not empty or exhaust themselves completely into the lands of the latter and which run afterwards into public rivers; such water courses are also designated "public," because part of them is public domain. The right of pre-emption (chufaa) is not applicable to these water courses.

Second. "Private" water courses (nehrihass) which run within the limits of the property of a given number of persons and whose water is exhausted and disappears upon such property without re-appearing to form another confluent. Pre-emption rights are only applicable to such water-courses.

Alluvium deposited by a stream on the land of a private individual becomes that person's property; no one else can lay claim to proprietary rights thereto.

Herbs of natural (wild) growth upon lands the property of no one in particular are *ex commercium;* the same with herbs that grow upon private property unknown to the owner; but if the latter waters his land or incloses it with a view to prepare it for cultivation, then the herbs growing thereon become his property; no one else can appropriate them, and he who gathers them is held responsible therefor.

By herbs are meant such plants as are not artificially watered; mushrooms, for instance, are included therein, but trees are not. Trees of natural growth (*i. e.*, wild growth) upon mountains which have no owners (djibali moubalra) are *ex commercium*.

Trees of natural (wild) growth upon the property of any one belong to the owner of such property; nobody can cut them down without his authorization. He who grafts a tree becomes the proprietor of the shoots and fruits thereof.

If anybody occupies a thing *ex commercium* he becomes the exclusive proprietor thereof.

Examples: The water which a person draws from a stream with a receptacle becomes his undisputed property, and if a third person consumes it without the owner's permission he is held liable therefor.

The occupation of a thing must show intent; consequently he who has placed a receptacle with the intention of collecting rain-water becomes the owner of such water. The same with water accumulated in a basin or cistern; but the rain-water found in a receptacle not expressly placed for such a purpose is not the property of the owner of the receptacle, and other persons may appropriate such water.

It is necessary in the occupation of water that it does not run continually; so for instance, well-water which filters through is *commercium*. He who consumes the water thus obtained by infiltration, even without the proprietor's consent, is not held liable for damages.

Again, water is not considered as having been appropriated where as much enters a basin on one side as escapes on the other.

Every one may enjoy a thing *ex commercium* on condition that such enjoyment causes injury to no one.

None can prevent a person from occupying or appropriating a thing *ex commercium*.

Everybody can utilize the waters of public streams for his lands, and may for this purpose, or for the purpose of constructing a mill, dig canals and ditches or trenches, on condition. however, of doing no injury to any one. Works which cause an inundation, those which completely exhaust a stream or which prevent boats (barges) from floating, are to be interdicted.

Man and beast may drink of the waters not the individual property of any one. The right of "chirb" (*i. e.*, the right to use water for irrigation and for the consumption of animals) of water courses, not public property, belongs to the owners of these streams (courses); any other persons, however, may drink therefrom. Thus no other person than the owner can serve himself of the waters belonging to a community or of a ditch, trench, or well, for irrigating purposes; but he may drink therefrom and even water his animals, provided the number of these be not so large as to damage the water course, the canal, ditch, trench, or conduit; he can likewise draw water therefrom with a pitcher or pail, and carry it to his house or garden.

Those who possess a brook, stream, basin, or well upon their lands, whose waters are renewed by nature, may prevent any one who wants to drink therefrom from entering their property; but if there exists no other water *ex commercium* in the neighborhood, the owners are obliged to either offer the use of their water or allow their lands to be penetrated; and, in case they fail to offer their water, those who wish to drink may enter the property, provided no harm is done thereto by damaging, for example, the edge of the wells or the water conduits.

One of the coproprietors of a common water course can not, without the permission of the others, cut a channel, ditch, trench, or gutter; he can not change his "turn" or share of the enjoyment of the water established *ab antiquo* nor cede such right to a landed proprietor who has no right to the waters of such a river for irrigating his field or watering his cattle. The authorization to perform these acts given by the other coproprietors could be evoked by these latter or by their heirs.

In all contestations touching drinking water or water for irrigating purposes, the rules, regulations, and usages established *ab antiquo* are to be enforced.

The waters of rivers, streams, springs, and other water courses, passing through the lands of a village or a city are the property of the community and must be distributed, as has been the practice *ab antiquo* in such a manner as to secure a supply to each landed proprietor during certain hours, either weekly or fortnightly.

Every owner of land knows the exact time and quantity of water to which he is entitled, and in almost every village there is a civil officer who is charged with the duty of looking after the proper allotment and distribution of the water among all the inhabitants.

As clocks and watches are not commonly in use among the peasantry, the time is measured by various devices, such as hour-glasses, etc.

Besides the Beirut Water Works, noticed under the head of "general remarks," there exist in Syria no irrigation works which supply water against payment, and the Turkish Government has no other interest, nor claims any other right to rivers, streams, springs, and other water courses than to place an increased valuation upon the lands irrigated therefrom, and to levy a comparatively heavier land tax.

(5) *Character of climate in irrigated region and nature of soil.*—The climate of the coast region is warm and damp. Thermometer ranges from about 40 to 90 degrees Fah. (in the Lebanon and other mountains

the range is from 10 to 20 degrees less in the winter and from 5 to 15 degrees in the summer.)

The climate in the interior is generally dry, but with greater thermometric range, say 25 to 30 degrees and 90 to 95 degrees Fah. The following table will show the average readings in Beirut during a period of ten years:

Thermometrical observations taken at the Syrian Protestant College at Beirut, Syria, from 1879 to 1889.

Month.	1879.	1880.	1881.	1882.	1883.	1884.	1885.	1886.	1887.	1888.	1889.

December	60.38	59.50	60.80	61.00	60.60	63.60	62.40	61.60	62.50	58.33	......

No statistics for the interior are known to exist.

The soil throughout almost the entire Vilayet of Syria is of a heavy clayey (argillaceous) nature, which, in drying up, becomes very hard, causing it to crack. In Beirut and other localities the experiment of using sand to improve the soil has been successful, but on a more extensive scale, and upon large tracts, this process would perhaps not prove practicable or feasible.

The character of climate is generally very good in the plains, but better in the mountains; the lands not irrigated are of course the most salubrious; the non-irrigated districts in the "Hauran" (east of Damascus) are considered by far the best, next come the regions to the north, then the Baalbek district, the plains of the "Bekaa" or "Cool Syria," and the districts of "Hasbaya" and "Rashaya." The land around Damascus is all irrigated and the soil is very fertile.

Annual rain-fall or other precipitation.—Along the coast, near Beirut, the annual rain-fall averages about 30 to 38 inches, but in the interior it is much less. One authority estimates it as low as 15 inches, while another makes it from 15 to 50 inches, or an average of 32½ inches. The rain-fall for Beirut for a period of ten years and six months is herewith annexed.

Rain-fall at Beirut, in inches, from 1879 to 1889, observed by the Syrian Protestant College at Beirut.

Annual average during ten years, 35.146 inches.

No statistics are kept of the amount of the annual rain-fall in the mountains and the interior, but it is variously estimated at from 15 to 50 inches, according to locality.

The precipitations are: Dew during the summer and the fall more or less plentiful. Very plentiful in spring, sometimes sufficient to ripen the grain, when rains cease early.

In February, March, and April hail-storms are not uncommon. If they occur late they are apt to destroy the mulberry leaves and the vine.

Snow falls on the mountains and in the interior, but no statistics are kept of the quantity.

Generally the country is at least five months without any rain at all, and a month after the last rain-fall the land is dried up to the depth of the roots of the trees, causing a total cessation of all vegetable life, unless irrigation is resorted to. May is the last month in which rain falls, but the copious down-pours really cease with the end of March or beginning of April.

(6) *Antiquity of irrigating systems, etc.*—All the existing irrigation works are of considerable antiquity, some date from time immemorial. On the right banks of the Dog River, about 5 miles north of Beirut, there still exists an old aqueduct, built upon arches and partly cut through the solid rock, running along the river side, which is said to date back to the time of the Roman occupation. The present use is to convey water for the irrigation of a vast tract of land, and to furnish the domestic supply for the village of Jumi, etc.

The ruins of another aqueduct, where the water was conducted over river and dale, are still to be seen in the valley of the Beirut River, about 8 miles above its mouth.

The water-works and conduits of Damascus, Tripoli, Homs, and Hamath are also of great antiquity, and the water is conducted by means of canals of masonry; or where this was impracticable, through earthen pipes and sometimes also through stones scooped out for this purpose.

The ancient canals in the plains of Mesopotamia, between the Euphrates and Tigris are still extant; but they are choked up with the accumulated rubbish of centuries, which, with a little energy and hard work, however, could easily be removed. (See also the report of the "Acca-Haifa" district and the annex to the "notes on irrigation" in the Vilayet of Adana.)

No maps or publications bearing upon the subject of irrigation, etc., exist in the province of Syria.

GENERAL REMARKS.

Under irrigation are usually placed lands lying along the foot of a mountain, from which rivers, streams, springs, or other water-courses flow, and which, by reason of their gentle slope, adapt themselves admirably for irrigating purposes.

In Beirut the area under irrigation extends about 5 miles in one direction and 8 or 9 in another, and the necessary supply of water is furnished by the Beirut River, conducted through five canals. Another strip of varying width and about 12 miles in length runs along the Mediterranean Sea, and is irrigated by the waters of the Dog River, the powerful spring of Antelias and other springs of minor capacity.

The irrigated lands in these districts are planted principally with mulberry trees for the silk industry, besides all kind of vegetables and garden stuffs.

At Tripoli the irrigated lands consist mostly of orange groves, about 5 miles square in extent, which, however, there is no lack, for the river that flows down from Mount Sannin (of the Lebanon range) furnishes an abundant supply, sufficient also for the ancient Tripoli city water-works. From Tripoli northward there runs a narrow strip of land between the sea and the mountains of about 1 to 2½ miles in breadth and about 16 miles in length, irrigated from the waters of springs and rivulets which have their sources there. Onions are the principal product of these lands; they are annually exported in large quantities in small sailing vessels. In the interior of the country, wherever there is artificial watering, "durah" or maize is generally grown, and is said to be quite remunerative; but it will not prosper without water.

Between Tripoli and Homs, in the valley of the Nahr "Jabir" (River Eleutherus), large tracts of lands are thus year after year planted with "durah." The crop per acre it has not been possible to ascertain with precision, but it is asserted by an eye witness that the best-looking of these fields would compare very unfavorably with the corn fields in Illinois, for instance, and that they would probably not produce much more than one-half the average yield of American farms. Upon the highlands (plateau) traversed by the river Orontes there is very little irrigation, for the river itself has, in the course of centuries, imbedded itself so deeply that the ancient water conduits can no longer be utilized and new ones have not yet been constructed. The conveyance of water in general is by means of canals or ditches expressly dug for this purpose, where they do not already exist, or where the water does not run of itself; the canals are usually very old, but are not kept in very good repair.

The waters of springs are carried into cisterns or tanks built of masonry, well cemented, which are usually emptied each day; large reservoirs are unknown in Syria, and the maxim among the natives in force is: "That irrigation is only profitable where the water runs unaided by man," that is to say, where condicts and consequently pecuniary outlays are unnecessary. Their ancestors were apparently of a different opinion, judging from the numerous works left by them scattered broadcast over the land.

Of modern irrigation and water works, the Beirut Water Works take first rank; they are the property of an English stock company, which furnishes Beirut with an excellent quality of drinking water at fixed rates, as well as a needful supply for irrigating purposes at reasonable charges.

Sidon a few years since built a pipe line to convey the waters of a spring or springs, situated about 2½ miles distant, into the city; and the municipality of Homs, three years ago, also contemplated the introduction of water works, but the project failed through the opposition of the city of Hamath, which apprehended a decrease and even a scarcity of water for its own supply.

Several efforts have been made by an intelligent and enterprising mechanic, established in business in Beirut, a citizen of the United States, to introduce mechanical and steam power as a profitable means of artificial irrigation. The first attempt made by him was in a region lying between Tripoli and Antioch, a broad plain traversed by a number of rivulets, whose beds, however, had become so deep that canals could no longer be made serviceable as conduits or conveyances of their waters, especially as there was not sufficient fall or headway.

A rich Arab who had seen the irrigation works in Egypt, conceived the idea of applying them practically to his lands situated in the district above mentioned and went so far as to order a machine of five horse-power. The pump was a "pulsometer" with 4-inch pipes, and the water had to be raised to an elevation of about 30 feet. The pump was guarantied to lift 750 litres or 166⅔ gallons per minute; it worked for forty days, fulfilled all its expectations, and would have been capable of irrigating an area of at least 80 acres in extent; but it appears that the fuel proved too expensive, wood being scarce and coal very dear, so that the experiment has been for the present at least abandoned.

A second attempt was made in the spring of this year in "Hazmyeh," in the neighborhood of Beirut, and notwithstanding that the water had to be elevated fully 130 feet, proved entirely successful.

The water is first raised about 10 feet from a well dug close to the Beirut River, by means of a cylindrical pump worked by a steam motor of three horse-power, and then forced through iron pipes along a hill to the height of 120 feet into a basin holding about 90 cubic meters, 3,543 cubic inches of water, for irrigating purposes. The basin can be filled in about six or seven hours, and the capacity per hour therefore is about 14 cubic meters, or 551 cubic inches. The investment seems to have proven an entirely satisfactory one in every respect.

A "Hallonday" wind motor has also been in operation near Beirut for over four years, which raises water to a considerable height and works satisfactorily. In general, irrigation as practiced in Syria does not entail any greater or other expense than the cost of maintaining the canals, conduits, etc., in good repair; but this, it must be repeated, is not always done.

Irrigation, as has already been shown, is regulated entirely by usage and well established rules, and every parcel of land has a right to the use of water for certain well fixed length of time. For instance: A small proprietor near Beirut has five acres of land; every Friday he can take as much water during six hours as he may need to thoroughly saturate his land; if he fails to take advantage of his privilege, he simply forfeits it without being indemnified therefor. Where water is scarce, as in many places in the mountains, it is often divided into hours and even fractions of hours, and good care is taken that no one receives or takes more that his allotted share. The sole owner of a spring—a rare occurrence, however—may of course use the water thereof at his own pleasure.

It is worthy of remark that in Mount Lebanon the waters of every spring, no matter how limited its capacity, is caught up into cisterns of good solid masonry, and is utilized for irrigating and domestic purposes, and no matter how steep the mountain sides or how poor the soil, the smallest available and tillable space is planted with onions, vegetables, marrow, or egg plant, and three and sometimes even four crops are thus produced each year.

The lands in Mount Lebanon are exceptionally well kept, and the population is principally composed of Christians (Maronites and Greeks, etc.), and Druzes, who are quite prosperous, and whose destinies are presided over by a Christian governor-general.

If the foregoing notes do not contain much of practical value or importance for the purposes intended, they may at least serve to impart some interesting if not useful information regarding the people of the oldest country, and of their ancestors the Phœnicians, which may not be generally known in the United States.

ANNEX B.

IRRIGATION, ETC., IN THE DISTRICT OF ACCA-HAIFA (SYRIA).

From materials furnished by Consular Agent J. Schumacher and Civil Engineer G. Schumacher.

The Acco-Haifa district and the region of the Hauran probably offer little in the way of irrigation that will prove of much value or interest, for the purpose of the State Department would appear to be to secure information of a practical character on a larger scale.

Interrogatory No. 1, "areas of land under irrigation," etc., of which the succeeding five interrogatories are merely an elaboration, can be summarily answered by the statement that there practically do not exist in Gallilee, in Nablus, or in the Jordan Valley any irrigation works in the full sense of the word as understood in the United States, and that land under irrigation in those districts is almost wholly unknown, forming but an infinitesimal—probably not more than the two-hundredth—part of the whole arable land.

In the Jordan Valley, on the Hûlé (sea of Merom), north of the Batîhâ and south of the Lake of Tiberias, also in the Wäd el Arab and Wäd el Tanjibe, the Bedouins irrigate small parcels of about 10 to 60 acres, upon which "durah" (maize) is grown, yielding annually two and even three crops. This result is due in part to the exceptional climate of the Jordan Valley with its tropical heat—a perfect hot-house—to the rich alluvial soil washed down from the basalt mountains, and also, perhaps, chiefly to the great abundance of water in the Jordan and Huromax (Arab, Sheri'al el Menädise); whereas the higher regions of Palestine and the littoral of the Mediterranean Sea are comparatively too poor in water supplies to enable their inhabitants to irrigate their lands to any great extent.

The irrigation process in all these districts supplied by water is of the simplest and most primitive character. In the early morning or shortly before sunset, young Bedouins in a semi-nude state may be seen roughly constructing from stones and earth a temporary dam to obstruct the waters of a stream or wadi (valley) while others provided with broad hoes dig little ditches, through which they lead the overflowing waters to be distributed over the parcels it is intended to irrigate, allowing the water free course in the lower lying lands, thus inundating or rather completely setting them under water. These manipulations are of daily repetition; the dams have to be regularly rebuilt, for the pressure of the water causes their daily destruction, and it is interesting to watch with what assiduity and perseverance these Bedouins are continually remaking and renewing the little ditches or canals which need their unremitting attention.

Reservoirs, basins, tanks, etc., do not exist, and the systems in practice here will therefore scarcely commend themselves to the inhabitants of more progressive countries.

Here and there, along the sea of Tiberias, remnants of ancient Roman irrigation works may be met with; but they are in such a deplorable state of dilapidation that of their original construction only a catchment basin remains near the head of the spring and a portion of a conduit (in masonry) is also yet in a fair state of preservation. The original character or the practical application of these ancient works can, however, no longer be established or recognized; for the Arabs not only made no use of them, but allowed everything to fall into decay and ruin, preferring the antediluvian ways of their own ancestors to the innovations of the Roman intruders.

In response to interrogatory No. 4, it may be said that "the system of water distribution," etc., depends wholly upon local custom as regulated among the different communities themselves. If several inhabitants of a village, for the purpose of irrigation, desire to utilize a spring in common they will use and distribute the waters thereof in conformity with local tradition as sanctioned by the municipal authorities; uch at least is the custom or practice in this vicinity. In all cases the proprietary ights of a village spring remain vested with the community, and the spring itself an never be sold.

The climate (question 5) in the irrigated districts of the Jordan Valley and in the rable lands bordering the Lake of Tiberias is, on the whole, rather insalubrious, ngendering malarial fevers caused by the evaporation (exhalations) during the heat f the day and the rapid cooling off at night; in other words, owing to the sudden hange and wide range of temperature.

For habitation, irrigated districts are carefully avoided in these parts, and as a rule ly negroes are capable of withstanding the deadly effects of the miasmata.

According to careful observations and measurements in Haifa during a period of welve years, the Phiviometer registered from 19.60 to 34.04 inches per year; last ar it reached 33.86 inches. The yearly average, however, may be taken to be 26 hes.

A draw-well in almost universal use in these regions, and by far the most practical and cheapest method of irrigating small parcels and gardens, is the "Hanani," a sketch of which in its improved form as in use by the Haifa German-American Colony is annexed herewith.

The "Hanani," as used by the natives, is of a much more imperfect and primitive construction than that of the colonists.

It may be worked by either donkey, mule, or horse (wholly unattended), and can be utilized to a depth of 150 feet. The size of the well buckets decrease in proportion to the profundity of the well to allow the "Hanani" to be worked by a single animal of either of the above species.

The amount of water raised diminishes in consequence with the increasing depth of the well, and the following table will serve to illustrate the practical results observed:

Place of observation.	Depth of well.	Amount of water raised per hour in gallons.
	Feet.	
Haifa	25	5,200 liters* = 1,144⁴⁄₉ gallons.
Haifa	30	4,000 liters = 889 gallons.
Gaza (Palestine)	146	2,500 liters = 555½ gallons.
Sea of Merim	15	6,500 liters = 1,444⁴⁄₉ gallons.

* Four and a half liters equal 1 gallon.

Of course the employment of steam would greatly increase these figures.

These quantities will vary according to the working capacity of the different animals employed, and the above figures were obtained by well-nourished animals, resting one hour after every three hours of consecutive work. The principal basin is generally replenished in from six to eight hours. It is constructed of masonry and well cemented, and ordinarily was 20 feet in length, 18 feet in width, and 7 to 8 feet in depth.

The main basin empties itself into a smaller one, 4 feet square by 2 feet deep, from which the water is conducted directly into the main irrigating canal, made of masonry, and situated in the most elevated part of the land, which feeds the numerous little ditches that distribute the water over the garden or field to be watered. The "Hanani" is of great durability and seldom needs repairs, especially if the water is free from saline particles; it is of the simplest construction and can be handled by the most inexperienced person.

REPORT ON IRRIGATION IN THE CONSULAR DISTRICT OF MERSINA (ASIA MINOR), SYRIA.

In the Vilayet of Adana, Syria, there are about 4,740,000 acres of land cultivable, but no irrigation works.

In the plain between Mersina and Adana there are about 400,000 acres irrigable, and between Adana and Missis about 350,000, through which there are three rivers, the Cydnus, the Sarus, and the Pyramus flow, but up to the present there are no irrigation works. The consequence is that for the last four years part of the crops has been completely destroyed, and what has succeeded could not be produced at prices to compete against the American and Russian markets in Europe.

The Turkish Government, on the pressing demands of the agriculturists, have recently taken the matter of irrigation in hand, and His Excellency the Vuli Sirri Pacha asked me to assist him in making the necessary surveys and plans, and I have just handed him the plans to irrigate a portion of the plain from Tarsus towards Adana for a distance of about 15 miles, which can be done at a very small cost. The other parts of the plain, however, towards Adana and between this latter and Missis will cost about £400,000 to irrigate properly, and although this sum would be comparatively nothing compared with the results, yet the Government, in order to avoid this outlay, want to try to make these irrigation works "a la Turque" if possible, but unless they are carried out by a competent company I am afraid it will be a failure.

The principal crops grown are cotton of very short texture, about 16,000 tons; wheat and barley of second quality, about 25,000 tons; sesame seed of first quality, about 4,000 tons; raisins of very inferior quality, about 4,000 tons.

The soil is partly red and partly sandy. Rain-fall averages 22 inches per annum.

The antique irrigations simply consist of the cultivators in the immediate neighborhood of the rivers and mill streams taking advantage of the water passing their farms.

NOTE BY THE BEIRUT CONSULATE ANNEXED TO THE REPORT OF THE "MERSINA CONSULAR AGENCY."

In olden times the vast plains of the Vilayet of Adania,Syria, were entirely irrigated by the rivers that pass through them. The Romans were in the habit of damming out the required quantity from the waters of the Djihoun, Seihoun, and Cydnus, and, conducting it to the foot of the mountains, form a high level on both sides of the rivers, along the surface of the ground, accumulating earth on both sides of its banks, making in this way a wide, high canal, extending from the mountains on both sides of the rivers in various directions to the sea. The farmers had thus the water within their reach and could easily, and at little expense, by means of subsidiary canals, conduct any portion of it to irrigate their lands.

These long and ancient canals, extending from the foot of the mountains to the sea in all directions, are still extant, and need but to be freed from the rubbish that centuries have accumulated to be again serviceable.

REPORT FROM HENRY GILLMAN, U. S. CONSUL, JERUSALEM, ON IRRIGATION IN PALESTINE.

With the exception of Jaffa and its immediate neighborhood, there is no part of this consular district in which any extensive and systematic attempt at irrigation according to modern methods is made.

THE JORDAN VALLEY.

In the Valley of the Jordan, which contains from 500 to 600 square miles of some of the richest land in the world, and which is never visited by frost, being from 700 to 1,300 feet below the level of the Mediterranean Sea, and where, with its semi-tropical climate and facilities for irrigation, several successive crops, may be produced annually, only the most feeble and primitive methods of conducting the necessary water to the few and ill-cultivated fields are followed. This unique valley, capable, with proper agricultural treatment, of sustaining an immense population, has no settlement worthy of the name. The wild Bedouin Arabs range throughout its length and breadth, and in defiance of the Turkish Government, which have in vain attempted to drive them out, come and go at their own free will.

Small fields, gardens, or patches of ground are here and there cultivated in the neighborhood of some stream having its source in one of the perennial springs of the region. From such a stream the water is conveyed in shallow drains or ditches to wherever required, and is carried through the fields or gardens by still smaller channels, the water being shut off or let on simply by the action of the foot, opening the tray inlet, or blocking it up with a few pebbles or masses of clay, as may be desired. This is a habit as old as the oldest writings, and of which mention is made in the Bible. "Where thou sowest thy seed, and waterest it with thy foot, as a garden of herbs." (Deut. 11, 10.)

Only the common farm crops are cultivated; but they are of specially exuberant growth.

At Nablous, or Ancient Shechem, or Sychar, similar methods in general are followed. The comparatively few fields and gardens are well watered from the abundant streams which have their rise in the Mounts Gerizim and Ebal, making it a spot of beauty in the midst of wild and unreclaimed surroundings. In one or two instances here there have been made some efforts at a more enlightened system of irrigation, the water from the clear and copious springs being conducted by aqueducts of stone masonry, and more satisfactorly supplied. The result in the luxuriant gardens, in which most of the various kinds of fruits and vegetables suitable to the climate are found, testifies as to what might be accomplished were more intelligent, systematic, and thorough measures adopted.

Throughout Palestine a very little water produces a wonderful result. The soil, naturally fertile, immediately responds to the effect of the periodic rains. The bursting of the land into bloom after the first heavy showers of the rainy season is a sight never to be forgotten. The hillsides and valleys that through the dry season had lain burnt up and barren, like a calcined bone, are suddenly, as if by miracle, turned into a garden of the most brilliant blossoms; the scarlet ranunculus and anémone, pomegranate, and many other flowers and shrubs only known to us in cultivation, "making the wilderness and solitary place rejoice and blossom as the rose."

THE KING'S GARDEN, JERUSALEM.

In the valley of the Kedron, on the southerly side of Jerusalem, is the king's garden, which dates back to the time of Hezekiah, if not to that of Solomon. It is mentioned in Nehemiah (3, 15) where it speaks of "Siloah by the king's garden."

The few acres which are at present under cultivation here are irrigated in the usual simple manner. The source of the water supply in the celebrated pool of Siloah, or Siloam, a reservoir 53 feet long, 18 feet wide, and 19 feet deep, which is fed through a subterranean conduit by the overflow of the pool of the Virgin, an intermittent spring about one-quarter of a mile to the northward. The water is conducted from the former pool partly by underground drains, regulated by the most primitive of sluices into smaller channels in the direction required, where still finer ramifications or branches distribute it to the drills or rows in which the crop is planted; much as in the other instances mentioned, and with as little regularity or system.

In these garden plots all the ordinary vegetables and many kinds of fruits are produced in good quantity and of fair quality. And up the terraced slopes, even to the very walls of Jerusalem, some of the largest cauliflowers come to perfection, and are in the market in the months of February and March. This vegetable sells at the rate of three heads for 12 cents.

There is no special regulation as to the use of the water other than that of the most patriarchal kind, the owners of the adjacent land having free access to the pool for all requisite purposes, including household uses, and the watering of their flocks and herds. Much of the water is also brought into Jerusalem for sale in goat skins.

KING SOLOMON'S POOLS AND GARDENS.

About 8 miles to the southwest of Jerusalem are the wonderful pools of Solomon; while, below them, in the narrow valley of Urtas, lie the renowned gardens of the wise king, except the garden of Eden, I suppose the oldest recorded gardens in the world. These works are mentioned in Ecclesiastes (2-46) as follows:

> I made me great works; I builded me houses; I planted me vineyards; I made me gardens and orchards, and I planted, in them, all kinds of fruits; I made me pools of water; to water therewith the wood that bringeth forth trees.

There is little doubt, too, that the scenes depicted in that beautiful oriental love-song—"The Song of Solomon," found here their original.

Josephus also speaks of this place: "Very pleasant it is in fine gardens, and abounding in rivulets of water," and tells us that Solomon was wont to visit it frequently, describing him as driving out there in the morning sitting on high in his chariot, clothed in white, and surrounded by his handsome mounted guards, all of great stature, and in the flower of manhood, arrayed in Tyrian purple, and in armor, their long hair sprinkled with gold-dust. It would be difficult to overestimate the noble character of those remarkable works, especially considering the periods in which they were constructed.

The pools consist of three enormous reservoirs, partly cut in the rocks, partly built of massive marble masonry. Their dimensions are as follows: The upper pool, 380 feet long; breadth at east end, 236 feet; at west end, 229 feet; depth at west end, 25 feet.

The middle pool, which is distant from the upper pool 160 feet, is 248 feet long; it is, at east end, 250 feet broad, and at west end, 160 feet, while the depth at east end is 39 feet. The lower pool, 248 feet eastward of the middle pool, has a length of 582 feet; a breadth at end, of 207 feet, and at west end, of 148 feet; and a depth at east end, of 50 feet, having sufficient capacity, as Dr. Thomson has said, "to float the largest man-of-war that ever ploughed the ocean." Each pool overflows successively by regulated sluices into the next below it, in the order here given, the last pool emptying its superabundant water into the valley.

Those venerable structures are at the present time in an excellent state of preservation. They are said to have been repaired by Pontius Pilate, which would be about 1,855 years ago.

The source of the water supply is the sealed fountain of Solomon, at the foot of a hill a short distance west of the upper pool. This fountain is always kept locked, hence the name. A flight of twenty steps descend from an arched doorway into an underground vaulted chamber, where four streams of pure and cool water converge. This fountain also afforded in former times a constant and abundant supply of water to Jerusalem, a goodly stream being conveyed by the carefully and skillfully constructed stone aqueduct of Solomon, which demonstrates that they understood at that early day the principle of the syphon, having introduced it into the Holy Temple inclosure.

About two years ago, the less ancient Saracenic aqueduct being put in repair, the water was once more brought into the site of the temple area, and into the so-called Fountain of the Cup, which stands between the Mosque of Omar and the Mosque Al Aksa, and doubtless marks the site of the brazen laver made by Solomon for the ablution of the priests in their sacrificial worship.

But the aqueduct soon again lapsing into disrepair, the water is, at present, barely conveyed in small quantity as far as Bethlehem, of which town it is the principal supply.

Of the 75 acres of land below the pools, in the valley of Urtas, 25 are under cultivation, and are irrigated.

Independently of the pools, the garden lands of the valley are also largely watered from a separate copious spring, which has its rise in the side of the mountain and at the foot of the village of Urtas. The soil is a red clay, exceedingly fertile, and to this day the finest fruits and vegetables in the Jerusalem market come from these gardens.

Of the fruits produced may be mentioned apricots, peaches, nectarines, apples, prunes, plums, citrons, lemons, pomegranates, mulberries, figs, and grapes. The vegetables include peas, beans, beets, ockra, egg-plant, onions, leeks, garlick, potatoes, turnips, cabbage, cauliflower, carrots, cucumbers, pumpkins, vegetable marrow, tomatoes, and radishes.

About two-fifths of the land belong to three Europeans, and the remainder is owned by the native Syrian fellahin (peasants).

The distribution of the water is regulated by the old custom or system of "fassels;" a night and a day forming a "fassel." Each family owning land there knows, from time immemorial, its respective rights and share in the "fassel" of water. Some have an entire "fassel," and again the same is divided among the different members of a family to irrigate their respective shares of land. The water is carried from one plat to another by drains in the usual simple manner already described. The Europeans who own land there have made, however, a cemented conduit to convey their share of water into their ground. No statistics are obtainable, none ever having been kept, as to the duty of water per acre.

No special rent or fee is paid for the water used, nor are there any charges on the land in connection therewith, the only payments made being the usual government taxes, the werko (land taxes) and ushur (titles).

Solomon's Park, the Sealed Fountain, and the Aqueduct are public property, and are under the control of the Turkish Government.

JAFFA AND ITS ORANGE GROVES.

The town of Jaffa, looking down from its pleasant elevation, on the one side on the deep blue Mediterranean and on the other on its multitudinous palms and odorous orange groves, may well be considered entitled to its name, which, softened in the Arabic pronunciation to Jaffa, means "beautiful."

The orange groves and gardens and their system of irrigation, though they have been greatly extended within comparatively recent times, have unquestionably an origin of quite respectable antiquity.

(1) The area of land under irrigation at Jaffa would exactly include the space occupied by its orange groves, being nearly one-third of the cultivable ground belonging to the community, that is, of 9,000 acres of cultivable lands about 3,000 acres are under irrigation.

The orange and the lemon are the chief crops; but other fruits, such as citrons, limes, peaches, apricots, grapes, pomegranates, and melons, and all the ordinary garden vegetables are also produced in abundance, and of fine quality. The vine especially is of late receiving much attention, and within the last few years extensive vineyards have been planted. Neither the vine nor the olive, of the latter of which there are many groves, require any water other than the usual rain-fall.

The superiority of the Jaffa orange is world renowned, whether its size, juiciness, or flavor is considered.

In an average season oranges and lemons, together with other fruits and vegetables, to the amount of $335,000 have been exported from Jaffa. Besides this is the immense home consumption, of which there is no record.

(2) The sources of the water supply are wells which are fed by underground springs.

(3) The engine in use for raising the water is in every case without exception the so-called bajara or bayara, a modern machine of the most simple construction, driven by horse or mule.

Its principal parts are a whim-beam or capstan, with horizontal wheel attached moving a vertical wheel connected by shaft with a third wheel, which carries at its circumference a chain of pendant reversible buckets. A pole inserted in the whim-beam is fastened to the horse or mule, with the monotonous circuit of which animal the entire machine is set in motion, the wheel with buckets revolving in the well dipping up the water and emptying it into the conduit or tank. The tanks are usually close to the wells, and are cemented basins, built of stone. They are filled during the day, the water being distributed from them, through the various channels, during the night in order that the loss by evaporation may be reduced to the minimum.

There are about seven hundred of those bajaras at work at Jaffa.

(4) The system of water distribution, being entirely under private control, is governed by neither law nor regulation.

The quantity of water used per acre during the season of twenty-three weeks or one hundred and sixty-one days is 2.300 cubic meters, at a cost of from 20 to 25 cents per diem. Thus, for instance, the average expense for irrigating an orange-garden with an area of 5 acres would be for one hundred and sixty days, at 20 cents, $160. The value of the crops might be estimated at from $500 to $700.

(5) Owing to the peculiarity of the climate, the orange groves are obliged to be watered during the summer months, or rather during the "dry season," when no rain falls; that is, from May till October or November. The rain-fall in the winter months, or say from November till May, varies from 17 to 30 inches. The average temperature is, in the day-time, from 70 to 90 degrees Fah.; during the night from 53 to 56 degrees.

The soil in the orange groves is of mixed clay and sand, with rather more of the latter than of the former. Is exceedingly fertile, and is particularly well suited to the orange.

(6) As to the antiquity of the system of irrigation, the close resemblance of the bajara to the Spanish "moria," has induced many persons to imagine its being introduced here at some early period from Spain. But as the family likeness of these wheels to the ancient Persian wooden water-wheel is equally great, and as the Crusaders, in the eleventh century, are reported to have found the orange-tree (*Citrus aurantium*) already in Palestine, the actual system of irrigation may as well belong originally to this country, or to the East, and may have been introduced from Persia.

GENERAL REMARKS ON THE CLIMATE.

In addition to the facts already given respecting the climate of Palestine, I add the following remarks: It is evident from the statements of history, both sacred and profane, as well as from other testimony, that this country in former ages was not only under a more general and thorough state of cultivation as regards its agricultural districts, but also that it possessed extensive tracts of forests, which have long since disappeared. Consequently its rain-fall was more favorably regulated, being more equable in its distribution. The result would naturally be not only the temporary advantage of the improved growing crops, but the enrichment of the soil and the permanent benefit of the land.

At present, seasons of almost tropical rain are followed by the long dry period in which not a drop of rain falls, and nearly every green herb perishes and burns up for the lack of moisture. Swept by the resistless torrent of the "rainy season," the higher lands are stripped of their soil and entire districts are seen in which the bare and barren ridges of rock crop out like the bones in the skeleton of some gigantic animal.

The phenomenon of the "air cushion" is seen here to perfection. Before a rain sets in it generally takes several days of incubatory preparation before the result comes. Great clouds roll up and cover the entire heavens with their dense masses; but in vain they attempt to discharge their contents, or if they succeed in dissolving, the thirsty atmosphere drinks up the moisture before it ever reaches the earth; and this must continue until the intervening strata composing the "air-cushions" are sufficiently saturated to permit the rain to fall through, which then occurs in a violent and often injurious downpour. Deprived of the gentle mediation of the growing crops, and especially of the forests, which would have established the proper relation and a just equilibrium, through their continual evaporation, the parched ground languishes for the rain that is denied it, or that, when given, comes in almost an unwelcome shape.

During the serious drought of 1887 and 1888 this phenomenon was seen in an extreme degree, weeks, and even months, passing without adequate rain, though the greater part of the time the heavens were dark with clouds.

The intervening unsaturated "air cushion" drank up the contents of the clouds, as already described, so that little or no rain could pass through it.

It is thought that the agricultural colonies established here within recent years have already begun to produce a perceptibly beneficial effect in this direction, but probably it is too soon yet to look for any decided change.

REPORT OF W. C. EMMET, U. S. CONSUL, SMYRNA, ASIA MINOR.

There is no irrigation practiced in this or any other district of Asia Minor, except in kitchen or fruit gardens in the neighborhood of large towns.

In these cases the supply of water is from wells on the premises, and the machinery used is a large wheel-bucket pump, worked by a horse.

These wells are of various depths and the supply of water utterly fails in some during long-continued droughts.

No water-works or artificial lakes are to be found anywhere, although there are numerous rivers, streams, and lakes which could be adapted to overcome the effects of the dry season, which usually lasts from five to six months.

These water sources belong mainly to the Government, in some instances to religious communities (mosques), but the right to use the same can be obtained at moderate cost.

In this section the yield of crops depends on a merciful Providence in withholding rain during the growing and harvesting seasons; the ingenuity or industry of mankind takes but an insignificant part in producing large crops.

Although the largest revenue to the Government is derived from tithes on agricultural products, the over-taxed peasantry labor under great difficulties and receive no encouragement or assistance from the Government.

The area of irrigated land does not amount to 1 per cent. of the arable land in this province.

The annual rain-fall rarely exceeds 26 inches per square foot, in fact, that is considered an ample supply.

The proportion of irrigated surface is so small that no perceptible effect is made on the climate of the district. The soil is mainly a sandy loam.

THE INDIAN OCEAN.

REPORT FROM ALEX. R. WEBB, U. S. CONSUL, MANILA, ON IRRIGATION IN THE PHILIPPINE (SPANISH) ARCHIPELAGO.

Owing to the numerous streams that rise in the mountainous districts and flow through the low lands to the sea, as well as to the copious rains, which will average 100 inches during the year, irrigation is seldom necessary in the Philippine Archipelago. When it is resorted to the most primitive methods are followed. If the rainy season commences later than usual the rice lands are sometimes irrigated by damming the mountain streams and turning the water over the paddy-fields through small channels, and in some cases the very old-fashioned chain-bucket windlass is used. This is a simple contrivance, composed of a number of small, water-tight boxes, formed into an endless chain by means of stout rope or leather bands, which run over a roller anchored in a river or creek, and a windlass on the bank turned by hand or cattle power. This is also used, in some cases, during the dry season on the lands where "zacate" or swamp-grass, which is fed to horses and cattle, instead of hay, is raised. On the low lands near the coast, where the rivers and creeks rise and fall with the ocean tide, sluice-ways and gates are sometimes used to flood the zacate lands during the dry season. These fields are seldom more than an acre or two in extent, and a comparatively small quantity of water is needed to flood them. The sluice-way is usually about 1 foot or 18 inches square, and when the tide rises the gate is left open until the required amount of water has entered, when it is closed and remains so until more water is needed.

On an estate belonging to the Dominican Fathers between Calamba and Bruan, and on another owned by the Augustinian Fathers near San Francisco de Malabon, both situated on this island (Luzon), some irrigation is done during the dry season by turning aside the mountain streams on the zacate land, and near Carite, about 27 miles northwest of Manila, a small stream is conducted through an iron pipe for about one hundred yards for the purpose of irrigating the paddy and zacate fields when water is needed. As a rule, however, the only irrigation received by the rice fields is from the rain-fall. The rice is planted about the commencement of the rainy season and is harvested shortly after the opening of the dry season, which seldom continues more than three months. The atmosphere is always moist at night, and heavy dews keep the earth damp and prevent the vegetables from drying up.

There is no portion of the archipelago where irrigation is conducted on an extensive scale and no means are known here by which the total area can be ascertained. All the irrigation is done on small patches of land and at private expense.

There are no storage works nor any general system of water distribution for irrigation. The Spanish water laws are in force for the government of the water supply used for household and street-sprinkling purposes in Manila, but among the general laws there are none upon the subject of irrigation.

AUSTRALIA.

REPORT FROM G. W. GRIFFIN, U. S. CONSUL, SYDNEY, ON IRRIGATION AND WATER CONSERVATION IN NEW SOUTH WALES.

There is perhaps no question that has attracted so much general attention throughout New South Wales and the other Australian colonies as that of irrigation and the reclamation thereby of arid lands. Royal commissions have been appointed in the colonies for the purpose of conducting inquiries in regard to the best means for distribution and conservation of water. The peculiar physical formation of this great island continent, as shown in the absence of lofty snow-clad ranges of mountains and great rivers, had added an element of difficulty to the inquiries of the commissions.

In my report entitled "Irrigation," transmitted to the Department of State in 1887, I endeavored to summarize the results of the New South Wales water commission inquiry. My report was republished by the Government of this colony in book form, and a copy will be found along with the publications I send herewith under separate cover, a detailed list of which will be found at the end of this report. Since that date the commission has made a final report, and a copy of this is also forwarded in the same manner.

It will be seen from the final report that a considerable portion is taken up with a discussion of the various plans proposed for the utilization of the waters of the rivers Murray and Darling. The following are the conclusions at which the commission arrived as the result of their investigations:

(1) That on water conservation mainly depend the prosperity and the development of the whole extent of the central and western divisions of this colony, and that though less required in the eastern division, it will add in many places there also in an important degree to the productions, and therefore to the value of the land.

(2) That as the land-holders, as a general rule, are quite equal to the task of providing sufficient water for the stock which the land can carry under present conditions, Government works for supplying water to stock are required only on a limited scale, and generally only on traveling stock routes.

(3) That the great object of water conservation in this colony, and particularly in the country west of the dividing range, is irrigation.

(4) That the purposes for which irrigation is chiefly required are (*a*) to provide fodder and grain for horses, cattle, and stud sheep; (*b*) to afford supplies to be kept in reserve for saving stock of all kinds in bad seasons; (*c*) to produce fruit, vegetables, and miscellaneous crops, and (*d*) to increase generally the productive powers of the land.

(5) That any well-considered and properly executed project for irrigation in the country west of the dividing range would afford a good direct return on the capital invested, and would be a distinct benefit to the colony at large.

(6) That legislation on the subject of water rights is a matter of pressing necessity, both to protect the rights of the state and to foster and encourage local and private enterprise.

The severe droughts in Australia, recurring periodically, constitute the most serious difficulty against which the people have to contend.

AREAS OF LAND UNDER IRRIGATION.

Irrigation works in New South Wales have only been carried out on a very small scale by private enterprise by the squatter, a term applied to the occupiers of land in Australia, to provide fodder for working and stud stock, and by the culturist for orchards, vineries, and gardens. I am informed by Mr. A. Pepys Wood, civil engineer, that no attempt has been made to irrigate agricultural holdings as such. The efforts, however, that have been made, limited as is their scope, have been found valuable, not only to the parties directly concerned, but to the public, as showing the wonderful results to be obtained from the soil and climate of the western districts, especially when a certain supply of water is available for watering. When this supply has been constant the results are said to have amply repaid the owners and to prove the large profits to be derived from such works if carried out judiciously on a lawful scale.

The area of irrigated land in New South Wales is at present so small as to be scarcely worth taking into consideration. It is true enough that a few individuals have irrigated portions of their lands at their own expense, but the absence of any well-defined laws on riparian rights goes far to prevent the people from utilizing the surplus waters of the various rivers and creeks. The main dependence of the Australians, thus far, for their water supply has been on dams, tanks, and wells.

In the Lachlan district a number of farmers have practiced irrigation on a small scale. Mr. T. Towser erected a pump about a mile from Forbes where there is a bend in the Lachlan River. The plant cost about £600 ($2,920). The plant consists of a six horse-power engine, a five-inch centrifugal pump, and 75 feet of piping.

The pump lifts the water to a height of 38 feet and has power to bring up 2,500 gallons of water per hour. Mr. Towser, during the drought of 1888, irrigated 12 acres of vines and fruit trees. He flooded the land four times. To water half an acre of land necessitated the use of the pump nine hours and he estimated that the 12 acres absorbed 2,600,000 gallons of water. Mr. Towser, speaking of his experment, said:

> I could hardly get props enough to keep my trees from breaking down under the very heavy load of fruit, while other orchards not irrigated, in the district, yielded a very small quantity of fruit.

The Lachlan soil, with the help of irrigation, will grow the finest fruit in the southern hemisphere. The fruits produced are numerous and include many varieties of oranges, lemons, citrons, pears, peaches, apricots, nectarines, quinces, figs, loguats, grapes, and strawberries. The fruit, which had to be sent a long distance to market, is described as unsurpassed in quality and, notwithstanding the high cost of freight and poor facilities for handling it, realized a good profit. It is proposed to reduce the cost of irrigation on this property by using a 10-inch instead of a 7-inch pump. Irrigation is used in the same district by the Messrs. Eadles & Co., who have a 9-inch pump for irrigating about 800 acres of grass land suitable for high-class stock, also a 7-inch pump is used for a smaller tract. Both pieces of land have carried eight to ten heep to the acre, while other stock farms, not irrigated, were literally uined by the drought.

It may be well to mention that Forbes is a town on the river Lachan, 250 miles west of Sydney. It has a population of about 3,000 inhabitants and it is rapidly becoming a center for the trade of a large section of the country around. The town is supplied with water filtered from the Lachlan, laid on in pipes at a considerable cost. The district contains about 10,000 inhabitants and carries 1,000,000 sheep, 10,000 horses, 5,000 cattle, and 2,000 pigs. In one year 8,315 acres were planted in wheat and produced 100,519 bushels.

Mr. Gatenby, about 25 miles from Forbes, irrigated in 1888 90 acres of land, which was laid down under grass, lucern, maize, and orchard. He used a 6-inch pump and he estimates the cost of irrigation at £2 ($9.73) per acre.

Mr. Gatenby stated that with a larger pump he could reduce the cost to about 10 shillings ($2.43) per acre. He found that lucern only required half the quantity of water necessary for ordinary grass. His grass land, which was watered once a month, carried eight sheep to the acre, and his maize land produced 100 bushels to the acre.

I learn from the third and final report of the royal commission on the conservation of water in New South Wales that at Windbar 7 acres yielded 30 tons of lucern hay per annum, under irrigation, at a cost of £3 ($14.60) per ton, during a drought when chaff delivered cost £23 ($111:93) per ton. It was estimated that the experiment with irrigation on his property resulted in a saving of £1,000 ($4,866) in the year.

Again, it is stated that at Tapio 18 sheep to the acre were maintained in splendid condition on a patch of 22 acres of irrigated land, while on the surrounding country 13 acres barely sufficed to keep one sheep alive; and further, Mr. N. Sadlier, of Albemarle, stated that on an area of 3 miles square, irrigated by the flow of flood-waters over low-lying land, he kept 8,000 sheep in the middle of summer and had a good lambing, while the same land, when not irrigated, did not carry 1,200 sheep. The only difficulties which seemed to present themselves were in regard to maintaining a permanent supply in the river to make irrigation possible during the time most needed—a prolonged drought—and the want of practical knowledge to employ the methods of irrigation.

It will be well enough to mention here that the farmers who have tried irrigation are highly gratified with the results, and in most cases their profits have doubled and trebled more particularly where the irrigation was used in the natural grasses of the country and with lucern, maize, and sorghum.

I could give many instances where irrigation has been adopted with unvarying success, but the areas are mostly small, probably not exceeding a total of 50,000 acres. In the colony of Victoria, however, very large areas are being rapidly placed under irrigation.

SOURCES OF WATER SUPPLY.

The sources of supply of water for irrigation are from rivers, creeks, tanks, and wells. The shortage of water supply extends over such vast areas of country as to be a source of astonishment that no well-directed effort has been made to conserve at least a portion of the supply falling during the tropical rains, especially in the northern territory.

With reference to the works situated on the rivers, the requisite supply of water has been obtained by pumping. For this work the centrifugal pump is generally used, though in some cases, such as for orchard and garden irrigation, direct acting pumps or the "Blake" or "special" type are used. It is said that none of the western rivers, except the Murray, can be relied on for irrigating large areas, unless works be constructed to impound an artificial supply. Certainly with some rivers, such as the Namori the supply in long-continued dry seasons is even inadequate for the small areas being dealt with at the present time.

The discoveries of subterranean fresh water north of the Darling River and the immense supply being obtained from some of the artesian bores point to a near development of irrigation on a more or less extended basis in that region. In the country south of the Darling the water in nearly all the wells that have been sunk is said to be brackish, which, together with the mineral matter contained in it, is unsuitable for irrigation. Were this not the case the depth (averaging 100 feet) would preclude its use for this purpose except when drawn by windmills, as fuel for motive power in most places where these wells are is reported to be scarce and expensive. It remains to be proved by boring whether at a greater depth an artesian supply of fresh water can be obtained; but as the geological formation is entirely distinct from that north of the Darling, it is said to be very doubtful if the same results will follow deep boring.

I have visited a property on Oxly street, Queensland, where water strongly impregnated with salt was used for irrigating the soil for growing lucern. The owner of the land was gratified with the benefits of such irrigation, and he held the opinion that many of the salt lakes in Australia would not be looked upon as a misfortune in the future. It was, however, pointed out to him that a continuation of the use of saline water must sooner or later result in the destruction of his lucern crop.

The apparent benefit from the use of salt water was apparent from the reason that lucern to a very large degree neutralizes salt in the soil. This has often been remarked in the alfalfa (lucern) field of California, and farmers account for the fine crops of alfalfa in southern California to the alkaline soil there. It is possible that on the high dry banks of a river where the soil is deep and good and with abundant natural drainage, that saline water might be pumped on lucern fields for a number of seasons without materially injuring the soil. Of course natural conditions would have to be taken into consideration, as for instance, in the case of the land to which I have lately referred, where the subsoil is thoroughly washed over by the heavy tropical rains.

Mr. H. C. Russel, Government astronomer, who has, since his arrival in the colony in 1870, devoted great attention to water supply, is very decided in the opinion that there is an abundant supply of underground water in the western districts of New South Wales. Many theories are advanced as to its origin. Some attribute it to a flow of water from the lofty mountains of New Guinea. When Mr. Russell pointed out, about ten years ago, the remarkable relations existing between rain-fall and the rivers of the west, he was told that his statements could not be true. No rain that fell would wet the ground 18 inches deep, much less afford water for underground supplies. With equal confidence it was asserted that the water which did penetrate into the ground was all dried out of it by evaporation, and further that the greater part of the Darling River basin was so flat that the water would not flow, and the rain, therefore, did not and could not find its way into the river. Mr. Russsell determined to wait the results of several years of patient investigation before speaking again. With regard to the first objection he has affirmed that in heavy rains water reached the Darling from the flat countries.

Evidence as to this fact was found in the rain-storm during 1885. In regard to the water from the mountains of New Guinea he said that, even admitting the theory, the area was insufficient. He did not think the water which flows into the Darling passed into the ground, although it was in evidence before the royal commission that parts of the Darling River basin were exceeding porous and allowed the water to sink down freely.

It is the opinion that irrigation in most parts of this colony from tanks is practically impossible, as water conserved in excavated reservoirs would cost about 6 shillings ($1.46) per 1,000 gallons, a price practically prohibitive. The future of irrigation seems to be largely dependent on the storage of some portion of the flood-waters now running to waste, and this can not be effected by expensive works confining such storage waters to the river channels, which, under the most favorable conditions, would only provide for watering a narrow belt on either side of the river channels, but must be effected by diverting and storing the water in the basins or lakes that nature has formed and into artificial basins or reservoirs constructed, as in America and other countries, among the hills, from whence it could be distributed by gravitation.

CHARACTER OF WORKS USED.

As already stated, irrigation in New South Wales has hitherto been confined to lands bordering on or adjacent to one or other of the rivers, and no works have been undertaken to increase or regulate the supply. Where the country is suitable the distribution is effected by channels or ditches laid out so as to conform to the features of the ground, and of sizes proportionate to the duty they may be required to perform. Pumping water for irrigation effected by Tangee centrifugal pumps, sometimes by windmills. The water is pumped up into storage tanks of iron or brick and then run off by gravity on to the land to be irrigated in pipes.

This method is, I think, peculiar to Australia. I have never observed it in California, or indeed in any other part of the United States with which I am acquainted. In portions of the country where the rainfall is tropical, and the soil becomes so dry that every drop of water is precious, tanks and pumps appear to work well, as there is no waste from soakage, evaporation, or capillary attraction.

The expense attendant on the above method renders its adoption on a large scale too costly. Orchards and the paddocks around many homesteads are, however, irrigated in this manner.

On the Torrens River, in South Australia, one of the farmers uses a pump with a four horse-power engine and the water is pumped to a height of 35 feet into a square brick tank, 10 feet long, 5 feet wide, and 2½ feet deep. More than half the tank is below the surface of the ground. The water when needed is distributed through 2-inch pipes sunk under ground and laid in different directions. At intervals of from 40 to 50 feet, stand-pipes communicate with the surface, and, being furnished with stop-cocks, the water is turned on or off at pleasure. From the stand-pipes canvas hose can be adjusted and laid on to the particular spots where the water is required. To facilitate the operation shallow trenches are scooped out near the trees requiring to be watered, and the water is led from one depression to another when the lengths of hose are insufficient.

At Emu Plains an extensive orangery is supplied with water in a somewhat similar manner, but here the water is received out of a well about 30 feet deep. The Tangye pump is placed 20 feet above the water and forces it into a number of 400-gallon iron tanks arranged on trestlework; 1,000 gallons of water are drawn from this well per hour. On the

Nepean River a farmer has an irrigation plant which is worked by a six horse-power Tangye engine, and the lift of water is 23 feet; from thence it is forced a distance of 850 feet to the storage tanks. The cost of the engine was £110 ($535), and the piping £50 ($243). The water flows from the tanks by gravity; open furrows are used. In the Riverine district, about Deniliquin, 481 miles southwest of Sydney, where the summer winds are very hot, fruit trees are kept in full bearing by mulching, *i. e.*, spreading litter, whether leaves or other matter, around the butts of the trees. Trenches 4 or 5 inches deep are opened in the soil about 5 or 6 feet from the trees; water is let into the trenches when required. It is said to pay to adopt these means even when the water has to be carted a considerable distance. The average rain-fall in this district is only about 16 inches per annum, but nevertheless fruit is very profitably grown.

The success attending artesian well-boring in various parts of Australia led to an investigation of the subject by Mr. W. Anderson, geological surveyor, of New South Wales, and I learn from his report that the Lower Cretaceous formation in which artesian water is known to occur extends over a vast area in the eastern half of the Australian continent, occupying the greater part of the interior of Queensland, a large portion of central and south Australia, and the northwestern plains of New South Wales. The southern extension of the Cretacis-Tertiary formation occupies a considerable area to the north of the River Darling in the neighborhood of Bourke. Mr. Anderson says it is astonishing that while this formation has been known for many years, pastoralists on the northern plains did not until recently realize the fact that they have beneath them an invaluable supply of water. He does not recommend boring for water where Silurian slates occur, for the reason that all the Silurian rocks of the district have a general strike of E. 20° N., and stand nearly vertically, therefore they can not possibly hold water in any abundance, and where Silurian formations occur there is always a thinning of the Cretaceous beds.

The principles which govern the location of water in the deep-seated beds of the formation, such as the Cretaceous and its subsequent rising to the surface as artesian water when tapped, are gravitation and the fact that a confined and continuous flow of water must rise to the level of its hydraulic grade. Mr. Anderson directs attention to five positions in which water may be found in the flat western country:

(1) In the Cretaceous formation itself;

(2) Between the Cretaceous formation and the Silurian bed-rock on which it rests;

(3) In the silted up Pleistocene river channels;

(4) In the immediate neighborhood of the present water-courses; and

(5) In the superficial portions of granite, as at Byrock.

The water in most of the wells that have recently been sunk is in quantity sufficient to indicate a permanent flow.

Such water is used for irrigation by gravity at very little cost.

SYSTEM OF WATER DISTRIBUTION, WHETHER GOVERNED BY LAWS OR CUSTOMS.

All irrigation works in New South Wales have hitherto been carried out by private enterprise. Each owner appears to be a law unto himself, and so long as he does not interfere with his neighbors' water rights is subject to neither rules, regulations, nor customs. In Victoria there is an irrigation act, and the necessity for passing a similar act in this colony is urged very strongly by both press and people.

It would be very difficult to form anything like a just estimate of the quantity of water used per acre in New South Wales. The consumption of water on the River Murray, which is the boundary between the colonies of New South Wales and Victoria, for farms in Victorian territory, and which cover a larger area, is, however, very considerable.

The peculiar river system of Australia has been explained in my published Report on Irrigation, and I will not now refer to it further than to say that the Murray is the most important river in Australia, and together with its tributaries drains an area of 27,000 square miles.

The Murray is navigable for boats of light draught for a distance of 1,700 miles from its mouth. In making its way towards the ocean it passes through a considerable portion of the colonies of Victoria and South Australia. New South Wales, although by her constitution, received from Great Britain, entitled to the control of the river, has taken no effective steps to utilize its waters for the purposes of irrigation.

Both the other colonies have, practically, taken possession of the watercourse, and I learn from a report just submitted to the New South Wales parliament, by Mr. J. E. F. Coyle, civil engineer, who has investigated the condition of the Murray, its navigation and use of water for irrigation, that out of one hundred and forty-three steamers engaged in the river trade, sixty-seven are owned in Victoria, fifty-five in South Australia, and only twenty-one in New South Wales. Mr. Coyle states that the other two colonies have ignored New South Wales, not only in regard to the trade on the river, but as to the use of the water for various irrigation schemes.

A number of wharves have been erected on the Victorian side by the Government there, together with sheds, plants of machinery, and other works which Mr. Coyle considers inconsistent with the ownership of the Murray by the colony of New South Wales. Since 1886, when the Victorian act authorizing the construction of works on the Murray for irrigation was passed into law, as many as sixty-three different water interests have come into force for irrigation purposes, and the quantity of water being now drawn from the river is exciting alarm among the people of New South Wales. These Victorians consume in summer 102,000 gallons, and in winter 61,800 gallons per twenty-four hours; also 46,579 cubic feet in summer and 161,618 cubic feet per minute in winter.

The Victorian Government has employed steamers in clearing the river from snags and other impediments.

The Government of New South Wales, of course, does not object to that, and it is scarcely probable that she would claim, in spite of her constitutional rights, a supreme control over all the advantages to be derived from the river, but she will undoubtedly object very seriously to any other colony doing so. The Victorians, however, contend that they are simply using the water that otherwise would be wasted, and besides that they have never been granted the right to use it for an indefinite period, for their Government in licensing irrigation works have expressly provided that water can be taken from the Murray only so far as it is in the power of the Government to permit.

Sir Henry Parkes, premier of New South Wales, in a powerful speech delivered in Parliament lately, pointed out what he deemed an aggression on the part of the Victorian Government upon the constitutional rights of New South Wales and very earnestly urged further legislation upon the subject.

The trouble is the question of right to control the waters of the Murray can not be settled by one colony alone, and will probably have to be dealt with at an intercolonial conference at which each of the colonies interested can take part, and an agreement reached by which the benefits of their principal water-way tribute may be shared alike.

CHARACTER OF CLIMATE, RAIN-FALL, ETC.

The colony of New South Wales extends through eleven degrees of latitude, it being entered on the parallels 28° 10′ and 37° 38′ south latitude, and between the meridians 141° and 153° 38′ east longitude. The area embraced within these limits contains 310,938 square miles, or 199,000,000 acres.

The climate extending through so many degrees of latitute, very naturally permits almost any variety, from hot to cold.

The northern part of the colony resembles that of the south of Italy, Spain, and Greece, while the southern portion is not wholly unlike that of northern California.

At Kiandra frost and snow prevail for a considerable part of the year; but on the plains of the interior the thermometer rises to 130° above zero, and sometimes there is no rain for eight months in the year.

The average annual rain-fall, according to a recent return supplied by the Government astronomer, Mr. H. C. Russell, was 23.68 inches for a period of fifteen years, from 1874 to 1888, the lowest average being for 1888, when it was 13.40 inches, and the highest in 1887, when it reached 34.39 inches. Mr. Russell has prepared the following table to show the average rain-fall in New South Wales for each year from 1874 to 1888:

Year.	Inches.	Year.	Inches.
1874	33.46	1883	17.96
1875	29.38	1884	15.86
1876	27.66	1885	19.48
1877	20.48	1886	26.04
1878	25.05	1887	34.99
1879	30.75	1888	13.40
1880	19.93		
1881	20.73	Mean, fifteen years	23.68
1882	20.11		

Mr. Russell states that the drought in 1888 was the most severe ever experienced, but during November and December rain fell and broke up the terribly dry weather.

During December, 3 inches of rain fell at upwards of two hundred recording stations, chiefly along the coast line, while the great western plains, which needed the rain most, remained to the end of the year in a state of drought. Not once during the year did rain enough fall on these plains to make water run on the surface of the ground.

On the Marano River the four months of winter passed with only .03 inch of rain. Even the native trees died for want of water in some places. In Sydney the average rain-fall for a month is about 4 inches; but over large areas in the west the rain-fall for the whole of 1888 was under that amount.

At South, on the Darling, it was 2.47 inches; at Menindie 2.82 inches. Mr. Russell remarks, that living in a moist climate near the sea, it is difficult to realize what such a record means in a dry, windy, hot place. The wonder is that plant or animal can live through it. Then, taking the mean of fifty places, the rain-fall for the whole colony was 43 per cent. below the average, and it is noteworthy that the rain-fall of 1887 exceeded the average by 42.7 per cent.; so the wettest and driest years on record are side by side showing a difference in rain-fall amounting to 85.7 per cent of the average.

When forwarding some valuable publications, Mr. Russell remarks in his letter to me of 28th September that, knowing what important questions could only be answered by statistics about rain, rivers, and evaporation, he began to collect them and to educate the people to keep rain records. In 1870 he found five meteorological stations at work. Now they number nearly one thousand. Records of the heights of the western rivers were begun in 1862 by Government officers, but they were not kept up In the annual rain reports are to be found every known rain-fall record for this colony. Mr. Russell has the control of the rain-fall records, and he states they are fairly complete for a young country, but the work of carefully gauging the output of the rivers has not yet been commenced by the Government. The records which he gives of the water at each place, the water velocities, are not measured, because competent officers for that work have not yet been stationed on the rivers. The velocities he has used were determined years since, and are assumed to hold good for the same height of flood for each year.

Since 1887, however, officers from Victoria have been systematically measuring the discharge of the river Murray, and have so far confirmed the results which Mr. Russell had obtained in the way indicated.

ANTIQUITY OF IRRIGATION SYSTEMS.

The remarks I have made in this report show that the various modes of irrigation practiced in New South Wales are wholly of recent date. The maps and publications which the Department of State direct me to obtain for the select committee of the Senate on the subject of irrigation are enumerated in the following list:

List of printed documents and maps relating to irrigation and reclamation of arid lands; sources of water supply; systems of water distribution; character of climate, and so far as relate to the colony of New South Wales.

1. Royal commission. Conservancy of water. First report of the commissioners. 1885.
2. Maps, diagrams, and plans referred to in the above report. 1855.
3. Royal commission. Conservation of water. Second report of the commissioners. 1885-'86. (Maps and plans are attached.)
4. Royal commission. Conservation of water. Third and final report of the commissioners. 1887.
5. Maps, plans, and diagrams to accompany the above report. 1887.
6. Royal commission. Conservation of water. First report of the commissioners. Abridged edition. 1886.
7. Royal commission. Conservation of water. Third and final report of the commissioners. Abridged edition. 1887.
8. New South Wales, her commerce and resources. By Consul Griffin. Report on irrigation. Pages 13 to 21. 1888.
9. Climate of New South Wales, descriptive, historical, and tabular. By H. C. Russell, B. A., F. R., A. S. 1887.
10. New South Wales. Physical geography and climate. By H. C. Russell. 1884.
11. The river Darling. The water which should pass through it. By H. C. Russell. 1879.
12. Some facts bearing upon irrigation. By H. C. Russell. 1883.
13. Notes upon the history of floods in the river Darling. By H. C. Russell. 1886.
14. Notes upon floods in Lake George. By H. C. Russell. 1886.
15. The source of the underground water in the western districts. By H. C. Russell. 1889.
16. Notes on the experience of other countries in the administration of their water supply. By H. G. McKinney, C. E. 1887.
17. Rivers of New South Wales. By H. G. McKinney, C. E. 1888.

18. Water supply in the interior of New South Wales. By W. E. Abbott. 1884.
19. Forest destruction in New South Wales and its effects on the flow water in watercourses and on the rain-fall. By W. E. Abbott. 1888.
20. On wells in Liverpool plains. By T. K. Abbott, P. M. 1880.
21. Metropolitan water supply. By Mr. James Manning. 1875.
22. Comparison between the Prospect and Kruny Hill schemes, proposing a high-pressure water supply for Sydney. By F. B. Gibbs, C. E. 1880.
23. Importance of a comprehensive scheme of water storage and canalyzation for the future welfare of New South Wales. 1881.
24. Tanks and wells of New South Wales. Water supply and irrigation. By A. P. Wood. 1883.
25. Results of rain, river, and evaporation observations made in New South Wales, 1879 to 1888. By H. C. Russel, F. R. S., Government astronomer of New South Wales. 1879 to 1888. (Ten parts).

The documents above enumerated are forwarded to the Department of State in separate cover.

Additional information, publications, maps, and plans have been promised me in time for transmission by next mail. I have reason to believe that the whole will form the most complete collection of literature on irrigation and water conservancy ever brought together relating to New South Wales.

LETTER FROM MR. JAMES WILSON TO CONSUL GRIFFIN ON IRRIGATION IN NEW SOUTH WALES.

Commercial, Pastoral, and Agricultural
Association of New South Wales,
40 *Hunter Street, Sydney, August* 28, 1889.

Sir: I have received from you questions on the subject of irrigation and the reclamation thereby of arid lands, with information that a special committee has been created by the Senate of the United States to investigate the questions involved.

The collation and systematic organization of reports on this subject from all parts of the world which your consular system affords can not fail to be of the greatest public utility, not only to the United States but to every arid corner of the universe, and it is to be hoped the committee will produce a report on a comprehensive scale which, when published, will prove of immense benefit to generations yet unborn.

For some time the Commercial, Pastoral and Agricultural Association of New South Wales has been engaged in noting the steps taken in this colony to deal with the arid lands in her vast interior and in collecting documents showing the great aid afforded by the Royal Society of New South Wales and kindred scientific associations for dealing with the local question, and in contrast with other countries, from more or less unofficial sources. I shall have much pleasure in placing these records at your disposal.

To my mind the question to Australia of water conservation, distribution, the development of underground reservoirs proved to exist, the economical adaptation of such, and rain fall observations as will minimise waste from the effects of periods of drought, by regulating supply, is as necessary as a mainspring to a watch. Upon the satisfactory solution of water difficulties depends the future development of this vast island continent, whose very existence a century ago was comparatively unknown. Of this continent New South Wales embraces a territory of 195,882,012 acres, and her present record of population is only a little over one million. To the United States our population and occupancy of territory when compared must form an insoluble problem; but the key is to be found in the pastoral stage of development in civilization during the nineteenth century, as practiced in Australia, and when we compare the numbers of the population actually outside our towns and cities the position will appear more explicable why we can not in the present stage point to existing irrigation and water conservation works and irrigable and non-irrigable areas and their results. The works in existence at present are only the outcome of private individual enterprise within freehold limits and bear no proportion whatever to the exigencies or necessities of the country at large, its rain-fall or river systems.

The mode of land tenure, the centralizing departmental form of government, and political inability to deal with so extensive a public estate upon a broad and national basis, are the true causes of neglect of and inertia towards our progress in this direction. It is from no want of consideration or inability on the part of our best men to grasp the importance of the situation, but from the general *laissez-faire* of our political economy which provides that all public works in the colony are conducted and controlled by government departments centered in the city of Sydney, not in touch with what might be termed local or district wants, and resenting interference with their prerogative unless under political pressure—a system which ascribes drought and disaster to Providence and fails to use means nature has provided for amelioration.

A more valuable compendium of information from many sources on irrigation in New South Wales than that presented in your consular report to the Department of State, Washington, republished by the New South Wales Government in 1888, does not exist, nor one more truthfully and fully describing this country; and I would respectfully suggest that that report be laid before the committee of the Senate. You have fairly pointed out the difficulty of riparian rights as they exist at present and the incidence of common law as prohibitive to deal with water conservation on a comprehensive scale, and you have cited the opinions of the water conservancy commission, appointed in 1884; it only now remains to supplement this by reference to their report in 1887, since published.

There have been no water-trusts created and no law changing riparian rights in this colony. The first bill in New South Wales to provide a water-trust, a municipality bill for the irrigation of a town common at Wentworth of 21,000 acres, on the New South Wales side of the river Murray, is now before parliament. Successive governments have for years past promised a scheme of local or district government which will embrace powers for dealing with water and irrigation by local trusts. Hitherto in this colony the public works for water conservation have been confined to constructing watering stations on the traveling stock routes in arid districts, wells, tanks, and dams. The government first recognized the necessity for such in 1869, and in 1888 it would appear from a statement relating to watering places, one hundred and forty-four in number, that an expenditure of over £270,000 ($1,313,955) had been made in construction and appliances, their maintenance costing over £25,000 ($121,663) per annum. These works have no doubt exercised a large and beneficial influence upon our pastoral progress.

I would suggest that you obtain from the government printer, Sydney, such official documents bearing on the subject as have been printed from time to time.

It only now remains to state that the government has conducted preliminary steps to carry out a scheme of irrigation and water-supply by canals, submitted to the water commission by H. G. McKinney, civil engineer; surveys are completed and the engineers are now taking levels for canals near Albury, on the Murray River. The main Albury canal will be 176 miles in length Jerilderie branch canal 33 miles, and the Tuppel branch 31 miles, a total of 240 miles. The estimated cost of this undertaking is £1,500,000 ($7,299,750), and the area to be irrigated 570,000 acres.

To water conservation and irrigation as presented in other countries, and especially in India, all our New South Wales and Victorian schemes must appear insignificant; but we are only a young country and a small community anxious to profit by the experience of others, and will gladly benefit by the results of the inquiry being made by the special committee of the United States Senate, embracing as it will consular reports from all countries.

I shall have pleasure in forwarding your inquiries in any way in my power.

I remain, with much personal esteem, yours faithfully,

JAMES WILSON.

G. W. GRIFFIN,
U. S. Consul, Sydney.

SOUTH AFRICA.

REPORT OF GEORGE F. HOLLIS, U. S. CONSUL, CAPETOWN, ON IRRIGATION IN SOUTH AFRICA.

South Africa has been described by some one as a country in which the rivers have no water. This is only too true during a portion of the year, while during the rainy season the rivers have a torrential character and the traveler must perforce halt at the river banks and wait for the rain to run by.

Until recently irrigation has been a matter of private enterprise and the works have been of the simplest and cheapest character. Wherever springs have been found it has been the custom to strengthen them by the building of a primitive dam above the spring's source, and the water so consumed is then conducted by a system of furrows over the area to be benefited. Where the water of rivers could be utilized the same system of furrows is followed and narrow strips of land on either bank of the stream are thus brought under a higher system of cultivation and large crops are the result of such a system.

Irrigation in this primitive way may be said to be the rule in the South African Republic, the Orange Free State, and in a large portion of the Cape Colony. In 1877 the Government passed an act for the promotion of irrigation, the principal provisions of which are as follows: Any three or more owners of land within any area in which it is deemed expedient to store water by artificial means for the purpose of irrigation may petition the government to proclaim such area an irrigation district, provided such petitioners shall be the owners of not less than one-tenth of the land in such district to be proclaimed. The governor may then dispatch an engineer or other competent person to the locality, where a public meeting of land owners is called, after due notice, and a report is sent to the governor as to the propriety of constituting such irrigation district. Should such report be favorable and receive the assent of two-thirds of the owners of land situated within its area, the governor may proclaim such district an irrigation district. The performance of all acts, etc., relating to irrigation and the storage of water in such proclaimed district shall be vested in a board having corporate powers, to be chosen from the land owners of such district. Every owner of land is entitled to vote at an election for members of uch board, and shall have one vote for each $500 valuation of land.

The charge and conservation of every natural river, stream, creek, nd water-course, and of every dam, pond, and embankment within the imits of an irrigation district which is by its nature common to two or nore of the owners of land within such district, and the absolute con- rol and regulation so far as the same can be effected by artificial means f the supply of water throughout the course of any such river, stream, tc., within such limits, shall be vested in the irrigation board of such istrict. Such board shall have power to cleanse, repair, and maintain n a due state of efficiency any stream, river, etc., as above; to deepen r otherwise improve such water-course, and to erect dams, reservoirs, tc.; in fact, to maintain, improve, and construct any works that shall e necessary for the proper storage and conservation of water for irri- ation purposes.

Provision is made for full compensation for any injury sustained by ny person by reason of the exercise of the powers of the board. The oard may also enter and take possession of any land, covered or un- overed by water, as may be necessary to carry out the purposes of is act. The board may levy rates at so much per acre in all land ithin the area which is irrigated or capable of being irrigated, provided at no land shall be taxed that is otherwise irrigated or improved by eans contemplated by the act.

Power is given the board to borrow money either by public tender or om funds provided by Parliament, in which latter case the governor ay loan to the extent of one-half of the value of the lands; such loan be a first charge on the same, and he may appoint officers to inspect ch lands and works.

IRRIGATION BY PRIVATE OWNERS.

Any owner of land, not within the limits of any irrigation district, oposing to improve the same by the storage or conservation of water l desiring a loan from the Government for such purpose, may make application for such purpose, giving bonds for the payment of the cost of investigation, and the governor may then cause lands, plans, estimates, and specifications of proposed works to be inspected and reported on. Provision is made for the loaning of money by the Government under due restrictions, which becomes a first and preferment charge upon the land at the rate of 8 per cent. for the term of twenty-four years.

Any mortgagee having claim on land must join with the holder of the title thereof in an instrument to be filed with the registrar of deeds. Provision is made for arbitration, the making of by-laws and regulations and penalities for the fraudulent taking or polluting of the water, or for obstructing or impeding the flow of water within the area proclaimed.

Two years later an act was passed by which provision was made for the loan of money by the colonial government to municipalities desirous of such assistance in carrying out works of irrigation, the terms of which are similar to the act of 1877, and provide that the interest in such loan shall be provided from the rates levied by the towns availing themselves of the provision of the act. The act of 1877 was amended in 1880, providing for the advance by the Government of the loan made by advances of one-fifth of the amount, and making provisions for repayment of the loan according to the following schedule:

Schedule A.

If the owner shall desire to repay the sum advanced in one year, the rent charge for one year shall be per centum, £106; if he shall desire to repay it in two years the annual rent charge shall be, per centum, £54 11*s.*; if in three years, £37 8*s.* 6*d.*; if in four years, £28 17*s.* 6*d.*; if in five years, £23 15*s.*; if in six years, £20 7*s.*; if in seven years, £17 19*s.*; if in eight years, £16 2*s.*, 6*d.*; if in nine years, £14 14*s.*, 6*d.*; if in ten years, £13 12*s.*; if in eleven years, £12 14*s.*; if in twelve years, £11 19*s.*; if in thirteen years, £11 6*s.*; if in fourteen years, £10 15*s.* 6*d.*; if in fifteen years, £10 6*s.*; if in sixteen years, £9 18*s.*; if in seventeen years, £9 11*s.*; if in eighteen years, £9 5*s.*; if in nineteen years, £8 19*s.* 6*d.*; if in twenty years, £8 14*s.* 6*d.*; if in twenty-one years, £8 10*s.* 6*d.*; if in twenty-two years, £8 6*s.* 6*d.*; if in twenty-three years, £8 3*s.*

Schedule B.

The present value of every £1 per annum rent charge shall be:

For one year, £0 18*s.* 11*d.*; for two years, £1 16*s.* 9*d.*; for three years, £2 13*s.* 6*d.*; for four years, £3 9*s.* 4*d.*; for five years, £4 4*s.* 3*d.*; for six years, £4 18*s.* 4*d.*; for seven years, £5 11*s.* 8*d.*; for eight years, £6 4*s.* 3*d.*; for nine years, £6 16*s.* 1*d.*; for ten years, £7 7*s.* 3*d.*; for eleven years, £7 17*s.* 9*d.*; for twelve years, £8 7*s.* 9*d.*; for thirteen years, £8 17*s.* 1*d.*; for fourteen years, £9 5*s.* 11*d.*; for fifteen years, £9 14*s.* 3*d.*; for sixteen years, £10 2*s.* 2*d.*; for seventeen years, £10 9*s.* 7*d.*; for eighteen years, £10 16*s.* 7*d.*; for nineteen years, £11 3*s.* 2*d.*; for twenty years, £11 9*s.* 5*d.*; for twenty-one years, £11 15*s.* 4*d.*; for twenty-two years, £12 0*s.* 10*d.*; for twenty-three years, £12 6*s.* 1*d.*

As early as December, 1881, no less than sixty applications had been made by the districts desiring to avail themselves of the terms offered by the Government. Owing to the peculiar character of the topographical features of the country and the fact that most of the rivers of South Africa are dry in the summer and flooded during the rainy season, a vast deal of scientific labor must be expended in order to determine the sites most advantageously situated for the construction of storage basins and other irrigation works. Topographical and geological surveys are being made under the direction of the Government.

It will probably be found necessary to make the formation of water boards compulsory, so that those land-owners situated above areas already proclaimed will be amenable to Government supervision in the conservation of their water courses. Wherever irrigation has been properly tried in the colony it has met with unqualified success, assuring large crops to husbandman and guarantying the stock-raiser against loss by drought.

From the lamentable reports now coming in from the up-country of the great loss of sheep by reason of the almost total lack of rain-fall this winter, I should judge a great impetus will be given to this question. Many farmers have reported a loss of from 10 to 50 per cent. of their stock, which would not have occurred had the districts been secured against drought by storage basins. Some idea of the enhanced value of irrigated land may be seen in the report made by one owner, who stated that his increased rentals would repay the loan for four years.

The most complete storage work completed in this colony, and the most important, is that of Van Wycks Valley, full reports of which with accompanying maps, Nos. 1, 2, 3, and 4, I send by book-post in to-day's mail. The rain-fall in this section is very irregular, the average for eleven years having been 10 inches, and in some years falling to 3 and 4 inches. The reservoir has depended on the catchment area of, say 240 square miles. This has been found to be insufficient for a full supply, and a furrow is now nearly completed through which the water of a neighboring river will be brought in, by which it is estimated that the water-covered area will be increased to 19 square miles with a depth of 27 feet.

The land under irrigation is held by the Government and is leased at a minimum price of 10 shillings per acre. The bailiff in charge has the sole control of the flow of water and uses his discretion in its supply, some land within the area requiring more water than other portions. Owing to many causes, the chief of which was ignorance of the character of the land—fostered by the report of interested persons who declared that the water would prove to be too salt for agricultural purposes, and who desired the work should fail and be abandoned, giving them a chance to acquire it—the poorest tenants, mostly assisted by the Government supplying seeds, were alone secured. Their success has, however, been so marvelous that the lands will soon be eagerly sought after. It is estimated that last year 1,300 acres were irrigated at an expenditure of an inch of water per month from the surface. The rain-fall over the whole colony is so irregular that I have taken the subdivisions of the colony for the purpose of comparison and have summarized the reports from an average of six stations in each district. The rain-fall for these districts for the year 1888 was as follows, in inches:

	Inches.
No. 1. Cape Peninsula	
No. 2. Southwest	53.84
No. 3. West coast	32.95
No. 4. South coast	15.18
No. 5. Southern Karroo	33.60
No. 6. West Central Karroo	17.59
No. 7. East Central Karroo	14.12
No. 8. Northern Karroo	16.15
No. 9. Northern border	11.43
No. 10. Southeast	8.84
No. 11. Northeast	28.17
No. 12. Tianskei	20.39
	25.00

The topographical features of South Africa are so peculiar that the system answering for one district is not applicable to others, while the rain-fall varies greatly as one leaves the coast and ascends to the various table-lands. In general, it may be said that, the land being almost entirely denuded of trees and bush, the rain is not drank up by the soil but runs rapidly over the surface, seeking its natural outlet to the sea, while the evaporation is very great, estimated at 6 feet at Van Wycks Valley, necessitating deep storage basins.

Streams which are alive the whole year are very few.

Boring for water has not been attempted on a large scale, but the experiments made in certain sections have given very encouraging results.

SOUTH ATLANTIC ISLANDS.

REPORT FROM THOMAS C. JONES, UNITED STATES CONSUL, FUNCHAL, ON IRRIGATION IN MADEIRA.

In answer to your circular and inquiries in regard to the system of irrigation now in practice on this island, I beg to submit the following report:

I can not answer your questions in as full a manner as I should like owing to the meagerness of statistics.

The public works here are of the most primitive kind. The same implements that tilled the soil and constructed the water-ways three hundred years ago till the soil and construct the water-ways of to-day. Stone is plentiful and labor is cheap; the island is furrowed with water-ways, but the new is no improvement on the old.

(1.) The area of Madeira is about 240 square miles. About one-half of the island is in cultivation. The whole of the sea-board is more or less cultivated by irrigation.

Where water is plentiful such crops as sweet potatoes, beans, cabbages, etc., are grown as high as 3,000 feet elevation above the sea; but maize is seldom grown above 800 or 1,000 feet, owing to the short summer season on the hills.

The area which is under cultivation by irrigation with sugar-cane, potatoes, onions, maize, etc., and almost at all seasons, and where, therefore, the population is concentrated, varies between 500 and 1,500 feet above sea-level, and may be estimated at a little more than one-third of the whole area of the island.

It is difficult to estimate the quantity of the crops grown, as the exports are pretty well limited to sugar, wine, onions, potatoes, and bananas. Sweet potatoes, which is probably the largest crop grown, beans, cabbages, are consumed in the home.

Almost all the cereals and food plants are grown in Madeira.

The wheat is of the bearded kind, with a hard, semi-transparent grain, and commands a better price than the imported. A large part of the vegetable subsistence is derived from the pumpkin tribe.

The banana is one of the best paying crops. It is confined below the 500-feet line. Oranges grow at an elevation of 1,500 feet.

(2) The water supply is derived from perennial springs and from the many gorges which carry off the water from the hills to the sea during the rainy season. After May these gorge streams are quite dry long before they reach the sea, their water having been drawn by the different levadas.

The north side of the island, being more precipitous and well-wooded, supplies its different levadas as well as several of those on the south side.

There are no reservoirs or catchment basins. They would be expensive to make owing to the precipitous nature of the hills, and it is doubtful whether the broken and rocky hillsides would hold the water unless the whole bottom were concreted.

(3) The character of the works used for distribution of irrigation water is levadas or open culverts. These are constructed of masonry or cut in solid rock at high levels. They pass through tunnels, over bridges, and along the sides of precipitous mountains, carrying the water to the cultivated lands below.

Some of these levadas are a few miles in length while others are 60 and 70 miles long.

(4) The system of water distribution is governed by custom and the flow is rated by the hour.

Some levadas deliver their whole contents during an hour or more as the proprietors of the water may be entitled to it. Others deliver say one-quarter of their contents at a time. The irrigator only requires the quantity of water at a time which will run along a furrow without washing the soil away.

The Sta. Lugia levada, for instance, contains 4,245 horns of water, to which there are proprietary rights acquired by purchase from the original makers or by inheritance. It now takes fifty days for each proprietor, of one hour to have his turn again; but he receives it instead by the quarter, every twelve and one-half days.

Besides the proprietary right there is in all levadas a right of water which belongs to the levada, and the committee of management for the year sells this water in January for the benefit of the levada, for repairs, etc., the water being plentiful at that season.

During the recent sugar-cane disease the price of an hour of water fell 50 per cent. in the Sta. Lugia Parish, viz, from $6 to $3.

Each piece of ground within the district of a given levad is entitled to its hours of use of the stream. For eight or nine months of the year the water is turned on to the proprietors as they may desire, but when the dry season sets in the committee puts it a "giro" or space of time occupied in making the tour of the whole district, which giro varies from 15 to 60 days, according to the extent of the district.

The "Levadeiro" or distributor of water is a salaried official, paid by the committee. He also collects a small fee of about 3 cents per hour per annum of the proprietary rights, and a higher fee on rented water. These fees are fixed annually by the committee.

When extensions or repairs of any magnitude are undertaken the money is borrowed, usually from the proprietors, and paid back in water or by rates levied over preceding years.

The foregoing applies to the old levadas, which were constructed by the proprietors.

No two levadas are alike in their volumes of water, in their velocity, or in their rates. In the neighborhood of Funchal the price of an hours rain in the season is from $5 to $8, while on the north side of the island it will never exceed $1 per hour.

The Government has, during the last fifty years, constructed levadas, which collected the waters in almost inaccessible gorges on the north side of the island, and conduct it to the warm south side. These waters are distributed to the cultivators of the soil at a nominal cost.

But when the Government levada is completed, and leaves the hands of the department of public works for those of the local, it gradually falls into ruin for want of attention.

No repairs can be made without estimates, and these have to be submitted to Lisbon for approval, and when approved, the time is generally so long that the original estimates are insufficient.

As water is the most valuable property in Madeira there is more quarreling about it than about anything else in the island. It is a fruitful source between the well-to-do and the poorer class. More people go to prison for stealing and tampering with water than for anything else.

One of the principal difficulties attending the management of the levadas was the want of a legal standing as corporate bodies of their committees. A quarrel between two levadas, draining their supply from the same valley, occasioned a lawsuit which has lasted now more than forty years. Within the last few years a law has been passed enabling the committees to incorporate themselves, with power to acquire property, and otherwise protect and improve their levadas.

They can purchase the land containing their springs, protect the forest and the trees along their lines. Every farmer of thrift has on his land tanks to store his water, and from these tanks little levadas distribute it when and wherever he wants it.

Water rights are held under title deeds, which specify the intervals at which the supply shall be given and the length of time it shall continue. Water is always of ready sale. If a crop fails from any cause the water for that land is sold to a more fortunate neighbor; though sometimes at a very reduced rate, as was the case in the time of the sugar-cane disease.

Under any system, it is hard for the poor. Their supply is scant, and they must receive it when their time comes, seasonable or unseasonable, day or night, and without tanks they can not care for or properly distribute it.

(5) The irrigated region is the coast belt, which during the summer season will produce crops that will ripen before the early autumn sets in. The nearer the seashore, with its consequent semi-tropical heat, the more valuable becomes irrigation.

The annual rain-fall in Funchal is about 28 inches; but the hills which supply the springs are almost always covered with clouds and wet mist, the water contents of which can not be estimated.

The soil varies in quality. That of the coast belt is calcareous tufa, with an admixture of vegetable matter, and is very rich. Wheat and barley are grown on the same land from generation to generation with hardly any application of manure.

The soil best adopted to the vine is a decomposed red tufa, especially where there is an admixture of stone with it. The hill regions have a stiff, clayey soil.

(6) There are levadas here probably 300 years old, but several of these have had their courses changed during political troubles and from other causes.

The levada, for instance, which now irrigates St. Vincente on the north side of the island, was constructed by the inhabitants of the Brava Valley on the south side, and was lost to them during the interegnum between the Spanish and Portuguese occupation. The Government is now constructing a levada, which will collect its waters in the hitherto quite inaccessible Inferno Gorge for irrigating the St. Vincente Valley, when it will restore to the Brava Valley the levada which originally belonged to it.

The source of this new levada is at the height of 4,700 feet above the sea, and after entering the valley it is intended to throw the water down a series of cascades with a fall of more than 300 feet.

A constant flow of a pint of water is sufficient to irrigate 5 acres of ground; that is, the water must flow into a reservoir and be used from that as required.

I have had translated the "Regulation for the Government of the Government Levadas of the Island" and have had it attached to this report. There are no maps or drawings of these works obtainable.

The engineers, contractors, and others who build our Government levadas come from Lisbon, and the plans, estimates, etc., are kept there in the office of public works. There are no publications that I can find.

Mr. John B. Blandy, of this city, is the largest land and water proprietor on the island. He has had more to do with the construction and working of these water ways, and is probably more of an expert than any person on the island. I am indebted to him for this report. He will take pleasure in giving the Senate Committee any facts that are in his possession.

PROVISIONAL REGULATION FOR THE GOVERNMENT IN THE DISTRICT OF FUNCHAL, THEIR ADMINISTRATION AND THEIR RESPECTIVE REVENUES.

FIRST PART—THE LEVADAS.

ART. 1. The regulation of the government levadas in the district of Funchal and the superintendence of the revenues of same are under surveillance of the treasurer of the same district, according to the decree published on the 10th of November, 1849, and the regulations for the administration of the public revenue, published on the 28th of January, 1850; also a Government grant, published on the 14th of September, 1860.

ART. 2. The levadas that belong to the government in the said district are the following:

Rabacal, in the parish of Calhéta, Fajaã dos Vinhaticos, in the parish of Santa Anna, Iuncal, and Furado, that irrigate Santa Cruz and Machico.

ART. 3. The Levada Rabacal will continue to be divided into two branches, one that irrigates Calhéta and Estreito, the other that waters Prazeres and Fajaã da Ovelha.

ART. 4. The Levada Fajaã dos Vinhaticos will continue to be divided into two parts, each containing an equal quantity of water.

ART. 5. Levada Iuncal and Furado are also divided into two branches, one that irrigates the parish of Santa Cruz, the other, Porto da Cruz.

ART. 6. To superintend the said levadas there will be appointed a staff of men, to be paid by the treasury of the home government.

ART. 7. The number of men, their rank, and respective salaries for each levada will be as follows:

Levada do Rabacal.

One director, with a salary of 17 per cent. on the revenues of the levada, calculated to be	$156.67
Two levadeiros (or water men), at $24 each	48.00
Two caretakers at 24 cents daily, each	175.20
Total	379.89

Levada Fajaã dos Vinhaticos.

One director, with a salary of 8 per cent. on the revenue of the levada	$43.00
Two levadeiros, at $16 each	32.00
One caretaker, at 12 cents per day	43.80
Total	118.80

Levada Iuncal and Furado.

One director, with a salary of 8 per cent. on the revenue of levada	$44.16
Two levadeiros, at $16 each	32.00
One caretaker, at 12 cents per day	43.80
Total	119.96

ART. 8. Besides the above items, which are for salaries, there will be another item of $180 yearly to compensate any deficiency in the salaries.

ART. 9. For directors of the levadas are appointed by government under the proposal of the treasurer, and keep the appointment as long as they are worthy of it.

ART. 10. The levadeiros are appointed yearly by the delegate of the treasurer under the proposal of their respective directors.

ART. 11. The caretakers are appointed by the delegate of the treasurer under the proposal of their respective directors.

ART. 12. The duties of the director of the levada are permanent and are as follows:

I. In the proper season for irrigation he is bound to see that the waters are fairly distributed.

II. To make as far as it lays in his power all the waters enter into the levada, so that the lessee of the water may have his share or more when his turn comes to irrigate his ground.

III. To have repaired any small damage made to the levada when necessary, having it in his power to call for help should he be unable to attend immediately to the said repairs.

IV. To avoid the loss of water should he know it, and give notice, etc., of same to the administrator of any damage done to the levada. If there are damages he may appeal to the department of government works.

V. To watch that the duties of the levadeiro and caretaker are properly carried out.

The director of the levada is answerable for its good keeping and also of the small canals that bring the water from the springs.

ART. 13. The duties of the levadeiro last during the irrigation season only. They are bound to deliver to each lessee the quantity of water that he rents to irrigate his ground according to a list given him by the clerk (or tax collector).

ART. 14. The duties of the caretakers are permanent and are as follows:

I. To live close to the levada.

II. To watch in summer and winter the levadas, that they are kept in proper repair, and that the springs are drained so as to enter the levadas.

III. To keep all the traps of the levadas open when it rains.

IV. To clear all obstacles that are carried by the water that may cause overflow.

V. To see that the levada is in proper repair, and to have repaired any wall that may have fallen over the levada, and to have removed any earth that may obstruct its course.

VI. To walk the course of the levada continually, or the part that he takes care of, to complain to his director of any theft of water, or if any damage that he can not repair.

VII. To watch the good keeping of the trees close to the levada.

VIII. To fulfill all the orders given him by the director as regards the levada.

ART. 15. The caretakers of the levadas are considered as forest-keepers, and are bound to watch the forest and bushes of his district complaining to the administrator of the locality should there be any damage to the forest.

ART. 16. The director of Levada Rabacal is bound to live close to the same levada, in one of the buildings, at a place called Rosadas, and to keep the houses clean when visitors stay there on their way to see the levada, and he is also answerable for the good keeping of the furniture, of which he has an inventory given him by the administrator, which there is a copy sent to government department of the district and one given to the caretaker of this levada. The director can have a house to live in conditional that he keep the tools belonging to the levada, and also those of the public works.

PART SECOND—TO LEASE THE WATERS.

ART. 17. To rent the water each levada must have a giro (that is a rotation of days) so that each lessee during the irrigation season shall receive the quantity of water he bargained for or bought.

The giros are fixed.—For the Levada Rabaçol is established every sixteen days or three hundred and eighty-four hours in each branch.

For the Levada of Fajaã dos Vinhaticos every sixteen days or three hundred and eighty-four hours in each branch.

For the branch of Inncol and Furado, that irrigates Santa Cruz, the giro is twenty-five days or six hundred hours.

For the branch of same levada that irrigates Porto du Cruz the giro is sixteen days or three hundred and eighty-four hours.

ART. 18. The leasing the said waters shall take place yearly in the month of March in the office of the administrator of the locality in the presence of the notary of the crown, and besides these, the director and levadeiros chosen by him are to be present to give any information that may be required.

ART. 19. For the said leasing it is necessary that placards, signed by the administrator, advertising the day appointed for the lease, should be posted in the most public places of the parish and at the church doors, stating the giro of the levada and the price per hour.

A copy of these placards shall be sent to the vicars of the parish where the levada runs, to be read before the mass is celebrated.

ART. 20. The giro of the waters in each levada can only be altered by the Government after the civil governor has given his opinion and the delegate of the treasurer.

ART. 21. The price of water in each levada is annually fixed by Government, according to information given by the different functionaries.

ART. 22. The lease of these waters are made so as to include the greatest number of landed proprietors whose grounds require water, making a just and equitable distribution of it according to the wants of each individual; those that in former years rented water and paid for it have the preference, and that the quantity demanded is indispensable to the soil under culture to be irrigated.

The water can not be rented to those who are in debt for any of the preceding years.

ART. 23. The notary will take the names of all those that buy water, the quantity of hours bought, the price which the lessee has to pay, all signing a document in which they bind themselves to pay the amount as soon as it is demanded.

ART. 24. Of the document above mentioned copies are to be made so that they can be sent, one to the treasurer by post, another to the director of the levada, and two others to the levadeiros. These last need not have the amounts of money written on them.

ART. 25. The original of the above document to be kept in the archives of the Government office after the necessary papers for collecting the amounts have been made out.

ART. 26. The day on which the waters are distributed placards are to be posted in the most public part of the parish, also on the parish church doors.

PART THIRD—TO COLLECT THE RENTS.

ART. 27. The collection of the water rent of the levadas takes place in August and is collected by the tax-collector of the parish.

ART. 28. That the lessee may know when the rents are to be paid the tax-collector must have placards posted up in the most public places, at least eight days before it commences, giving notice of, first, the place where the rents are to be collected; second, the day on which he commences to receive rents.

ART. 29. The lessee who can not pay during the said period has to pay 3 per cent. on the same amount or a fixed sum of 4 cents when the said amount comes to $14. The above is declared also in the placards according to Article 20.

ART. 30. The receipts given must be according to model No. 2 of instructions published February 8, 1843.

The list must be made out according to Article 24, before mentioned, and must be in the hands of the collector before the 15th of July of each year, according to practice already established.

ART. 31. The sums received from the rents of water will be booked as "revenues of the levadas," and the 3 per cent. on fixed rate as revenues of the levadas.

PART FOURTH—DIFFERENT DISPOSITIONS.

ART. 32. The administrator has the same duties to fulfill as regards the levadas as he has toward other national properties, to see especially that the services of the levadas are properly performed by those that are intrusted with it.

ART. 33. If the repairs of the levadas be so expensive as to call for the aid of the public works, the administrator of the parish is obliged to inform the delegate of the treasury that he may ask the civil governor of the district to have the necessary repairs made.

ART. 34. The appointment of the levadeiros must be made yearly, by the administrator, during the month of February.

ART. 35. The salaries are to be paid every quarter. Other trifling expenses attending repairs to be paid at the end of each month in which they are made.

ART. 36. To pay the salaries of the employés, as well as the different items attending the levada repairs, annual pay-sheets are to be made by the administrator and sent to the treasurer to be paid.

The balance-sheets, to be paid, must be accompanied by the directors' vouchers signed by the administrator.

ART. 37. If at any season the irrigation water is not all sold, the giro can not be altered, but the administrator must let the delegate of the treasury know.

ART. 38. If at any time there is not a competent director appointed, the delegate of the treasury in the district may appoint a person *ad interim* until he gets one to fulfill the place definitely. The appointment of the director can be made by the administrator and in that case he receives the salary of a director.

ART. 39. If the place of care-taker becomes vacant the director can appoint a person *ad interim*, until he definitely engages an individual, in the mean time he must acquaint the delegate of the treasury of the person he proposes.

ART-TRANSITORY.

To proceed with the lease of waters for the current year the price of water is as follows, subject to the approval of the Government:

In the Levada da Fajaã dos Vinhaticos and its branches, 70 cents; in Inncol branch, 60 cents; in the Furado branch, 50 cents.

If at any time the Levada da Fajaã dos Vinhaticos has not sufficient quantity of water for irrigation, for example, in the height of summer, the two branches are to be united by the mutual consent of both lessees the price then will be $1.40 each hour of water; that the lessee receives.

The other levadas are subject to the same conditions when there is a dearth of water and in that case the price is double.

HOME DEPARTMENT OF THE DISTRICT OF FUNCHAL,
March 28, 1862.

The delegate of the treasury.

FRANCISCO HAVIN DE SONTA.

Approved.

HOME DEPARTMENT OF THE DISTRICT OF FUNCHAL,
April 7, 1884.

The first official.

FRANCISCO JOAQUINN PESTANA.

REPORT OF HENRY PEASE, U. S. CONSUL, SANTIAGO, ON WATER SUPPLY AND IRRIGATION IN CAPE VERDE ISLANDS.

The subject of irrigating arid and cultivated lands in this colony is not varied or extensive enough to form the basis of a report such as requested.

Nature has been so unbounteous in her supply of fresh water to the Cape Verde Islands, that there are no lakes, rivers, ponds, or large streams, except during the rainy months, which are August, September, and part of October. But there are many springs on the islands of St. Antone, St. Iago, and St. Nickolas, issuing through the rocks at the base of the mountains, in the bottoms of the deep valleys and ravines. It therefore became necessary that the inhabitants should have settled near a spring. Yet about half the towns and villages on these islands are so remote from fresh water that all their supply is brought from 1 to 3 miles on donkeys or the heads of women.

QUANTITY AND MODE OF IRRIGATION.

It would be difficult to obtain any precise information as to the quantity of land under irrigation, as there are no reports or statistics on such a subject. Yet from observation, and information received from some land-holders, I should not underrate the areas, by stating that the only lands receiving irrigation during the dry season, which is from November to August, are a few patches of flat ground in the valleys below the level of the springs, cultivated as "garden plots."

The mode of irrigating is by making with a "hoe" (the principal agricultural implement used in this colony) a number of small trenches leading from the springs through the cultivated grounds,

EUROPE.

REPORT FROM DARIUS H. INGRAHAM, U. S. CONSUL, CADIZ, SPAIN.

I can not learn of any maps or works on the subject, though the latter may exist translated from the French, but are regarded as merely theoretical and of no interest or value to a people who have from the time of the Moors, and perhaps of the Romans, carried on practical systems of irrigation chiefly in the provinces of Murcia, Valencia, and Granada, and to a lesser extent in western Andalusia. In these provinces, especially Seville, which is watered by the Guadalquivir, whose valleys are rich not only in corks, grains, but in olives, oranges, palms, grapes, and other semi-tropical fruits, ditches are dug through the lands and fed from the river; and in other localities the irrigation is done by a sort of water raiser from wells, called norias, consisting of a chain of buckets going over and over as they come up from the well, filling and emptying by the operation, and propelled by a blinded animal, a horse, cow, ox, or mule, going round and round, and kept within the circle of the noria by a pole running from the head of the animal to the pivotal post. Thus secured he goes along all day long around the circle without driver or guide. In some cases a steam engine is in use among large properties, but the noria is of great antiquity. In Damiel, La Mancha, 3,000 norias are used, only in summer, and the same exist generally throughout Spain.

In Lorca, a town near Carthagena, where the land is salty and the river overflowed, an enormous dam has been built in recent years to retain the water.

As no statistics are published, I am unable to reply to some inquiries of the circular, but it is believed that the difference between irrigated and non-irrigated lands is as one to twenty-five in value.

There is no Government system or control custom regulating all, as it did in the time of those masters of irrigation, the Moors. For instance, at Granada a sort of court called the water court has existed by the customs of centuries, to pass on all questions of irrigation and rights between owners, and this court is regarded as high authority, dispensing exact justice and enjoying a reputation like none other in Spain. It is organized from custom; it sits at certain times at the Alhambra to hear causes, as it has done since the mediæval ages, its members coming on mules or horseback, and alighting before the bench provided for the hearings.

In one of the towers of the Alhambra a bell rings at different times of the night to indicate the flow of the waters of the Xenil and Darro, which have their confluence at this point and irrigate the vast Vega of Granada.

In this section I am not able to give the names of any experts on irrigation, as in this consular district the operations are limited as above described, but I would refer to Mr. W. Langdon, of Huelva, engineer of the Rio Tinto mines, who once furnished me an interesting paper on the teredo, a worm attacking submerged wood; and in Cadiz, Señor Don José Maria Conte, a distinguished writer and interested in agricultural subjects.

REPORT FROM CLODOMIRO PEREZ, U. S. CONSUL, CADIZ, SPAIN.

The immense importance and the successful solution of the irrigation problem implies, has justly attracted, and no doubt will always attract, a vivid attention in all agricultural countries, and as regards the European continent perhaps more especially so in Spain, where, owing to the heterogeneous character of the soil and climate, a judicious distribution and utilization of the water supplied by abundant rivers, brooks, and springs, or in certain regions, however not otherwise obtainable than by storage from rain-fall and underground sources, is, together with an obvious need, one of the most beneficial agents for general prosperity.

Water, apart from satisfying the peremptory purposes of quenching thirst, averting fire dangers, and contributing to public health and embellishment, proves a cheap and useful auxiliary of industries, but more principally a capital element, a solid guaranty to enhance and increase the agricultural production and all other interests inseparably associated with the yield of the soil, a branch that represents the most conspicuous and positive wealth.

Since in remote ages this rich and so oftentimes coveted territory entered the noble road of civilization and human progress, cultivators could not fail to become perfectly aware of the favorable influence exerted on the growth of plants, and consequently on the result of crops, through the opportune agency of irrigation, whether natural or artificial. It has been, therefore, the common aim of the Spanish people, as well as of those patriotic and enlightened rulers who have guided the destinies of the nation with a true devotion for the public welfare, to give a constant aid and all possible impulse to everything that tended to the protection and development of the water supply system.

The hydraulic works for irrigation carried out in Spain in ancient and modern times, although not yet completed to all the extent of which this country admits and even requires, show bold conceptions. They are in many cases magnificent, practical monuments erected by intelligent active minds, who thus have endowed large districts with the fruitful and lasting germ of the luxuriant life there enjoyed by past and present generations.

The treatise on "water and irrigation" (Aquas y Riegas, two volumes), which, as instructed by circular of May 2, 1889, I have the honor to send the Department of State with the present report, will, I am confident, afford useful information to the special committee appointed by the United States Senate to investigate into the matter of irrigation as practiced in Spain, and perhaps excuse diverse omissions I may incur.

While I respectfully call the attention of the Department upon said book saying that it is the only work published in this country which in every direction treats the subject in a reliable and exhaustive manner, I beg to mention that its author, Mr. Andrés Plaurado, is the chief forestry engineer for the district of Madrid and a qualified authority, both at home and abroad. He recently, in the name of the Spanish "Ministerio de Fomento" (the department embracing public works, agriculture, industry and commerce), took part in the discussion held at the International Congress of Paris on the utilization of the water of streams.

His views upon the subject "*De l'avenir des canaux d' irrigation,*" a remarkable essay, met the approval of eminent foreign scientific men.

Mr. Llaurado's work, "Water and Irrigation," contains an elaborate historical and technical description of the canals and reservoirs built in Spain; also useful suggestions, resting upon his practical observations, concerning construction, financial and economic results, and the best means to secure the success pursued in enterprises for irrigation.

First of all, I will now point out the prominent conclusions arrived at by Mr. Llaurado, namely:

It is an axiom that in northern countries irrigation increases the product of cultivation, especially in summer.

In southern countries irrigation becomes absolutely necessary, whether to remedy drought or to overcome the consequences of unequal rain-fall.

Reservoirs become absolutely necessary in Spain to store up water during the time there is rain, in order that the decrease produced in streams just when agriculture is most in want of it might be restored.

Irrigation undertakings must divide in two different classes:

(1) Irrigation works which can be achieved by the single individual effort.

(2) Irrigation schemes which necessitate the interposition and subsidies of the Government.

Private activity, from a financial stand-point considered, will be able to accomplish irrigation schemes, provided the rate consumers pay for water covers the expenses of working them, the amount of interest corresponding to capital invested, and a fair profit. Otherwise the business must result in a failure for private concern, while, though it can not be absolutely asserted, it is advantageous for the Government, whose ample unlimited means of action allow them to balance loss with profit.

What now is met with at the "Canal Imperial de Aragon" and at the "Canal de Urgel," under direct management of the public administration, clearly evidence that assertion. The construction of the first-mentioned canal cost the Government about 20,000,000 pesetas ($4,000,000). and since the reign of Carlos III, when it began to be worked, up to our days the immediate direct net produce earned by the administration aggregates the sum of 37,000 pesetas annually ($7,400), a notorious meager yield in proportion to the capital invested.

But the business, however, far from being ruinous for the State, has largely compensated the outlays by creating great sources of wealth, which deliver up to the public treasury a good part of their income.

It must not be overlooked that, in order to render mutually advantageous to companies and farmers the utilization of water schemes the irrigation tariff must be rated cheap.

The modest yet mighty sphere of private spirit is able to achieve with success many works in totality superior to the limited number of enterprises due to the initiative of the Government.

That does not mean the Government should be allowed to monopolize this kind of undertakings. They are not feasible for the Spanish Treasury in its present circumstances, when it is rather too much influenced by the oscillations of politics.

But the administration can promote such irrigation business as may aid the private companies by affording facilities to individual action, by making public the hydrological data, the investigation of which is not consistent with private initiative, and by framing accurate statistics on the rights for use of available public water.

As refers to the great works of canalization the Government ought to undertake the construction for its own account, and when they are finished cede them on fair terms to the irrigation syndicates, reserving itself the right of superintendence and protection, in order that the sacrifices made by the people may not result fruitless.

The Spanish Peninsula extends approximately over eight latitudinal and upwards of twelve and one-half longitudinal degrees; its periphery measures 3,300 kilometers; the surface of its soil comprises about 50,000,000 hectares (123,500,000 acres), with elevations exceeding 3,500 meters above the level of the ocean, vast table-lands, deep valleys, and nearly 2,000 kilometers sea-shores extending along four slopes, washed by different seas, and facing different cardinal points of the globe.

The contrasting conditions of climate enjoyed according to local circumstances can well be imagined; they are so manifold that in this sense, rather than a mere peninsular, Spain comprises by itself a vast continent joined to the rest of Europe through the mountain range of the Pyrenees, and partakes the scale of subtropical up to sub-Alpine temperature, with burning summers, as in the Sahara Desert, or glacial winters, as in Scandinavia. A glance at the hereto appended summary of meteorological observations gives a fair idea on the physical consequences which arise in various regions.

In the qualities of the soil all gradations exist, from the hardest and most compact clayish soil to that of the most loose and movable silicious nature, in all possible shapes, the evenest as well as the steepest and most rugged. It also differs in depth from the shallowest and most naked soil up to the most covered with vegetable layers; and as to the hygrometrical conditions from extreme moisture to the most complete dryness, from the least fitted to irrigation, and to such as is perpetually condemned to receive no other water than from rain-fall.

Of the total area of Spain (50,000,000 hectares) 40,000,000 hectares are cultivated for crops and pastures; about 2,000,000 thereof are benefited by irrigation.

Among other peculiar features common to the north coast of Spain the provinces of Santander, Oviedo, Biscay, and Guipuzcod, in which this consulate and its respective agencies of Gijon, Bilbao, and San Sebastian are located, partake of the most frequent and greatest rainfall in any part of the Spanish peninsula or in Europe.

I quote what Mr. Llaurado says, referring to the above-mentioned provinces:

> On account of the great moisture, the air being almost always in a state close to saturation, ordinarily no other farming grounds but the meadows require a suppletory irrigation. In comparatively dry summers, however, some orchards will be irrigated, principally on alluvial soils of new formation where the underlying stratum, consisting of loose pebble-stones, allows an easy permeability. Permanent meadows constitute the main basis of the agricultural wealth, for they are calculated to supply food for 400,000 heads of horn cattle and a good number of horses and sheep besides, as refers only to the province of Oviedo, and nearly equal proportionate ciphers are applicable for the remnant three provinces, especially for Santander.

In order to examine the cultivation of meadows as it is practiced here, we must suppose them divided in two groups, namely, irrigated and not irrigated meadows.

The first ones are generally lying on the declivities or on the valleys, in the neighborhood of some spring or brook, the water of which may be easily drained; and the last-mentioned meadows occupy the tablelands on the tops of mountains and all such places not much accessible for irrigating them by artificial means, which enjoy no other irrigation but that imparted by eventual rains.

The irrigated meadows, in their turn, form two groups, in the first of which are included those the products of which are consumed by cattle on the meadow itself, the summer harvest excepted, this being mowed and stored for stable food. In the second group are comprised the meadows the produce of which is mowed and cattle fed therewith when yet green, and which furnish, besides, the summer harvest like the meadow lands of the first group. In these irrigations last during all the year, and are only discontinued as long as the cattle are kept within the stable, this being done the months of April, September, and October, on fine days in winter, when tardy frosts are feared, and during twenty to thirty days before harvesting the hay.

Not irrigated meadows, in spite of the moist climate, yield considerably less than the irrigated ones, irrigation being, therefore, indispensable if it is desired to obtain abundant pasture and hay.

The remark has been already made that the water used for this kind of cultivation is either drained from brooks or from little perennial springs, as well because of the continuity and facility of their utilization as on account of the difficulties met with in the drainage from streams, the most part thereof offering deep beds and an excessive slopeness.

The system for irrigation of meadow lands most commonly applied in these provinces is that denominated "irrigation by inclined channels," or also "spike channels" (*riego por regueras inclinadas* or *regueras en espiga*). The distribution channels are devised nearly in the sense of the greatest slopeness of the ground; the irrigating channels connect with them and spread out to right and left hand.

A rapid sectional change takes place on the distribution channels at the point where they separate into branches with the irrigating channels. The last-mentioned channels, by having a gradually narrowing section from their parting point down to the opposite end, pour out the water by getting inundated. Another contrivance is also combined with this briefly described distributive system which consists of collecting channels called *azarbes*, dug on the natural lines of junction on the meadow ground terminating in an outlet channel. Sometimes, when the extent of the meadow is not considerable, or when the quantity of water available is but small, the collecting channels are changed into new feeding channels for the supply of other lots situated farther down.

Within the four provinces above named discrimination of three different climates and regions must be made, depending from situation, whether on the sea-shore, inland valleys, and mountains. The climate on the sea-shore is mild; orange trees can thrive in the open air. In the valleys the climate is fresh; there orange trees, as also grape-vines, only thrive on sheltered places. The climate on the mountains is cold; they generally in winter are covered with snow. Here lies the center of the Cantabrian Mountains, a branch of the Pyrenic Mountain range, with lofty summits, some of them as high as 2,678 meters above the level of the sea.

The highest temperature at the inland valley of Cabuerniga, Santander, during a period of three years (1872–1874), as recorded by the foresty engineer, Mr. Louis Calderon was 48° heat in the sun, 39° in the shadow, and the lowest, which, like the other extreme temperature, very seldom occurs, was 4° below zero. Many years the temperature never exceeds zero degrees. When the thermometer points out 8° or 10°, water generally falls on the mountain pastures lying highest, called *puertos* or "harbors," in the shape of snow.

The forestal and cattle raising industries are the most genuine and prominent riches in these provinces, especially in Oviedo and Santander. The structure of the soil consisting of narrow valleys surrounded by mountains with varied but for the most part too steepy slopes for a safe and commodious cultivation, it is obvious to say that the agriculture, limited to valleys and flat lands of small extent, can never attain a great developement. But, in exchange for the forest and cattle interests, there is proportionately immense room in the best conditions for success, as the frequent rain and continuous mists, covering almost constantly and at all seasons of the year those mountains, maintain a most suitable, fresh, and moist character to vigorous spontaneous vegetation.

The communal pasture grounds being abundant and of such good quality, natural meadows are, most of them, intended to harvest fodder for feeding the cattle during the time the atmospherical inclemencies hinder a direct grazing. As the period when this occurs is no longer than three or four months in the year, the cattle-raising industry is certainly susceptible of a far greater increase as soon as the meadow lands are more carefully cultivated and larger quantities of hay are produced. With the quantity of fodder indispensable for a head of cattle in other provinces, three heads will then be fed here, because the period cattle have to be kept in the cow-house is much shorter. A permanent keeping in the stall is not advisable unless the absurd principle should be established to abandon the enormous wealth the beautiful and vast grazing grounds of the high meadows (*puertos*) represent.

The system now partly prevalent in cattle-breeding is of course such as arises from the local conditions; in the West region horn-cattle are raised until two years old, whereupon farmers in the East region and on the sea shore devote themselves to raise the same up to full growth. In the first-mentioned region natural as well as high meadows (*puertos*) are abundant, while in the other parts that kind of meadows are scarce, and consequently cultivation-meadows become necessary.

One should think that in the Cantabrian coast, one of the rainiest countries of Europe, the system of drainage, rather than that of artificial irrigation, would often be applied. Yet irrigation is here of no little importance, mainly to obtain natural meadows and repair the irregularities of meteoric water used for other cultivators.

Irrigation is most frequently made use of here during the months of March and April, when grass begins to shoot up. The soil is left altogether inundated when strong frosts are feared, in order that the covers of water might protect the soil against the consequences of frost or ice. In normal years artificially irrigated meadow-lands produce greater harvest than those called "*praderas de secano*" or "dry land meadows," but in exceptional years of drought the irrigated meadows are the life-boats wherein farmers save their cattle.

Milk, so its products, butter and cheese, all of an exquisite natural flavor in these provinces, it can be affirmed, have no rival of higher standard in the world. It is obvious to reveal the secret of such excellent qualities, which consists in nothing else besides a good cattle race but the conditions of plenty of pure air and nutritive aromatic pastures. The cow breeds called "of Tudanca" and of "Campoo," in the neighboring districts of Cabuceniga and Régnosa, respectively, Santander, and the "Asturian" race, province of Oviedo, justly enjoy a great renown.

For centuries the mountain woodlands of Santander have been providing with superior timber (oak) the Spanish navy and merchant ship-yards, also (beech) cooperies for preparing barrels or casks for wine and wheat-flour exportations to the Antilles. They scarcely have escaped the total devastation that has been the fate of public forests in Spain.

The planting of trees to replace those consumed or cut from the parish forests was formerly compulsory for all citizens who enjoyed the rights to use the same. That duty is completely neglected; though it has not been repealed, it is not enforced as it ought to be.

I have thought it pertinent to make some digressions on the circumstances attending agriculture and cattle-raising, those two branches which form the great wealth of the mentioned provinces, because of their being so closely connected with irrigation.

On the whole, the geological and climatic conditions in this northern part of Spain keep the greatest resemblance with the counties comprising the "wealden formation," in the southeast of England, such as Kent and Sussex.

An agent which considerably modifies the damp character of this climate is the south wind. It acts like an enormous sponge to absorb the humidity, and as a natural stove where both the air and the soil are speedily dried up. The atmosphere acquires then such transparency that scarcely any gradual lines or shadows of varying distances on the horizon are perceived. It is peculiar to the south wind that immediately it ceases to blow it is generally followed with rain, and that while it is blowing on the coast, rain will most likely be falling on the elevated plateau of Old Castile. The winds which prevail longest in the year come from the west-northwest, succeeding the periods from the south. The east-northeast winds are those blowing in summer until September or October, when they maintain clear, dry weather for longer time.

In the provinces of the North, adjoining those where this consulate and its agencies are situated, irrigation by artificial means is practiced, more extensively at Leon, which borders on its northwest side with Santander and Oviedo. The Ecla Canal irrigates there about 13,000 hectares (32,125 acres). When its construction began (1859), the estimates amounted only to 625,000 pesetas ($126,000), but ten years later (1869) the sum of 3,250,000 pesetas ($650,000) had been expended. It carries a quantity of 6,480 cubic meters water per second. This canal was built by grant to a foreign private company. According to agreement the annual rate farmers have to pay for water varies from 19.45 pesetas to 97.27 pesetas ($3.89 to $19.45) for each hectare of land irrigated. Notwithstanding the yearly aggregate cashed by the company has been about 8½ per cent. on the capital invested, it does not produce sufficiently to pay the interest to capital, the expenses of maintainance, management, and of interest necessary for amortization. The company met with some embarrassment, perhaps, by not having secured through a formal written engagement how far they had to rely upon consumption of water. Until a year when extreme drought prevailed in the country, the attitude on the part of many farmers to subscribe for the use of the water for this new canal was quite reluctant, but then they obtained a practical conviction of the positive advantages derived from artificial irrigation to supply the absence of rain.

On the vast plateau of Old Castile the "Canal de Castilla" crosses a distance of 207.792 kilometers from Alar del Rey, Santander, dividing in two branches at El Serron, Palencia: one of them, the "Canal del Sur," 54.432 kilometers long, down to Valladolid, and the other, the "Canal de Campos," 78.929 kilometers long, to Medina de Rioseco," the center of cereal production in the North, called for this reason, by Spaniards, "*el granero de España*," or "the corn-barn of Spain." The section of the "Canal de Castilla" from Alar del Rey to El Serron takes the denomination of "Canal del North," and is 74.431 kilometers long.

The "Canal de Castilla" is an important water-road for transportation, navigated by barges carrying each about 33 tons; the water of it serves also as a motive force for a good number of large mills and factories. But the same is scarcely used as a means of artificial irrigation. Its most noteworthy works are seven locks on the "Canal de Campos," twenty-four on the "Canal del Nerth," and seventeen on the "Canal del Sur."

On the "Canal del Norte" section, the canal carries 4.47 cubic meters water per second, being distributed between the two branches in the proportion of 2.79 cubic meters to the "Canal del Sur" and 1.68 cubic meters to the "Canal de Campos." The uppermost part of the canal in the last-mentioned section is 15.55 meters wide, at the surface of the water 11.66, and at the bottom of the canal 5.83 meters wide; it has a depth of 1.93 meters. The towage-path along the canal measures 3.33 meters width in places where the earth had to be cut off, and 4.44 meters at the embankments.

The Pisuerga and Carrion affluents of the river Duro, are the feeders of the "Canal de Castilla," the construction of which, begun in the middle of the last century, was interrupted, and reached its completion during the reign of Queen Isabel II.

In normal years the want of moisture necessary to the growth of most cereals, wheat, barley, rye, etc., seems not to be much felt on the boundless-looking corn-fields of the northern provinces of Castile. The arable surface of the soil is deep and fertile, though the monotonous perspective of vast plain land impresses the mind with aridness, seeing that it is almost completely denuded of trees everywhere, for the prejudice is most prevalent there among cultivators "that trees are only good for sparrows to build their nests on and as places of shelter for the voracious winged enemies of plantations."

During the war of Crimea the shipments of wheat-flour from Castile, made at the port of Santander, amounted to enormous quantities. An enthusiastic fever then existed throughout Castile. The boasting phrase, "*Agua y sol y guerra en Sebastopol,*" ("Water and sun besides war at Sebastopol,") whereby Castilian farmers expressed their prosperous situation in those years, was so generally pronounced and repeated that it became a proverbial sentence.

A great number of flour-mills were erected on the canal, and the largest possible extent was given to the production of cereals. Those exceptional incidental causes by which the agriculture was favored have passed long ago; they are now not more subsistent. Farmers in Castile devote their care not only to cereals, but also to extend the grape-vine plantations, and must adopt all improvements in modern agricultural progress if they will keep pace with the cheap production of other countries. Irrigation will be of course a means to the profitable result of a varied cultivation.

The province of Logroño bordering with the back province Alava, is one of the agricultural districts where great benefits are obtained through artificial irrigation that makes it very productive in all kinds of fruits and vegetables. It is the richest orchard and kitchen garden in the northern region of the river. Elbro, the source of which is at Fuentibre (Fons Tiberus), near Reynosa, Santander. This river becomes navigable at Saragossa, supplies water for the "Canal Imperial," and some other of the most important irrigating canals, and no other river in Spain is more used for irrigation; the advantages it affords to agriculture are considerable.

At Logroño and the neighboring districts known all under the denomination of "La Rioja" good wine is obtained and mostly exported to France, and also shipped to other countries by Bilbao and Santander. Fruits and vegetables (capsicum, tomatoes, peas, etc.), are prepared in cans in important quantities for house and export consumption.

The practical and wise laws founded or issued by the Arabs during their domination in the south of Spain, in the provinces of Valencia, Murcia, and Granada, maintained there more specially by careful traditions, are the basis of the new laws framed for all irrigating corporation, who will enjoy certain privileges. These privileges consist substantially in the right that when as prescribed they unite in "Sindicatos" or syndicates, they can appoint their own independent courts, all proceedings being public, verbal, and the decisions of these independent courts (*Turados de Aguas*) or water-juries inappealable.

In Leon such syndicates exist, so in Logroño, but in none of the above-mentioned provinces of the North, where, for the reasons I have explained, artificial irrigation exhibits an individual, isolated aspect.

Engineers in the construction of some of their great hydraulic contrivances do, perhaps, only observe and copy the works of nature. There are no "lakes" formed by rivers in Spain to collect water for further distribution in "natural deposits;" to supply the same on suitable elevated places, sometimes in the mountain gorges, reservoirs, called "albuheras" or by the more modern name "pantanos," are built, where the water is stored up. *Acequia* (as many words of Arabic source) means exclusively irrigation canal.

In Valencia farmers have inherited with the valuable irrigation system of the Saracens also their good practical habits for agricultural. There they know what great value water involves. They always carefully look that the ground be well leveled in order that both the water coming from canals and from rain-fall is equally beneficial to the plants, because otherwise some parts of the soil will become covered with water while other parts remain dry, and in some others water will carry away the humus, salts, and oxides, the richest elements contained in manure to aid vegetation. Nobody knows as they do to retrench the flowers and buds when the plants are too overcharged, as they are aware that a smaller number makes fruits get ripe earlier and improves the quality. Nobody else knows better than those farmers how to select the precocious ears, one by one, with the purpose of ameliorating the species and accelerating the period for ripeness. The Valencia farmers remain constantly near their plantations, and through artificial irrigation they realize in that climate an abundant and incessant crop of rich products.

REPORT FROM J. L. RATHBONE, U. S. CONSUL-GENERAL, PARIS, ON IRRIGATION IN FRANCE.

(1) Areas of land under irrigation; compare with the non-irrigable and cultivatable areas when possible. Also, quantity and quality of crops grown?

The surface of irrigated lands is roughly estimated at 2,350,000 hectares. As cultivated lands are not generally irrigated, it is not easy to compare non-irrigated with irrigated lands. Pastures are the only lands generally irrigated.

The average production per hectare of irrigated and non-irrigated pastures is: Irrigated pastures, 37 quintals; non-irrigated, 31 quintals. This difference of 6 quintals represents a total value, in the first case, of 230 francs; in the second, of 190 francs, per hectare. Among the areas devoted to cultivating the vine, some are submerged, while others are irrigated. But the value of their produce depends upon other causes than irrigation.

(2) Sources of water supply, whether from rivers, streams, springs, lakes, wells, reservoirs, catchment basins, or tanks, etc.

The canals cut for purposes of irrigation all flow from rivers. In some instances attempts have been made, by means of artificial reservoirs, to increase the quantity of water yielded by the river. It was for this purpose, for example, that the reservoir of Oridon was constructed in the department of the Hautes Pyrénées. Its object was to increase the volume of water in the river Neste, from which flows the canal of the same name.

(3) Character of works used for storage and distribution of water. Forward published reports, if obtainable, in regard to any important irrigation and storage works.

The number of reservoirs above mentioned is still somewhat limited. The works carried out in view of distributing the water generally consist, first, of a principal canal, or chief branch through which the volume of water to be distributed flows from the river; second, of a small canal, fed by the principal one; third, of a net-work of streams, drains, and ditches which provide each land-owner with the quantity of water to which he is entitled.

(4) The system of water distribution, whether governed by laws, rules, and regulations, or customs, give duty of water per acre, *i. e.*, the amount used per acre and per season; the cost or rental to user; tenure of ownership of water, and whether the same be public or private, national or community.

The use of water for irrigating is regulated by the French code. The articles of the code bearing particularly on this point are the following:

> 643. The owner of the spring can not change its course when he provides the inhabitants of a commune, village, or hamlet with the water necessary for them; but where the inhabitants have not acquired or prescribed the use of the same, the owner may demand a compensation, the exact amount of which is to be fixed by an expert.
>
> 644. The owner of a property skirted by a running water which is not national property, according to article 538, has a right to the use of the water for irrigating his lands while it flows past them. The owner of ancestral lands traversed by this water may use it within the full limits of his lands, on condition he restores it to its proper bed before it leaves his estate.
>
> 645. If a dispute arises between the land-owners to whom this water may be useful, the tribunal called upon to give its decision in the matter shall conciliate the interests of agriculture with the respect due to the rights of property, and, in every case, with the particular and local customs and regulations which pertain to the passage and use of water.

The works executed for purposes of irrigation may be divided into two classes:

(1) Those undertaken and carried out by companies called syndical associations.

(2) Those undertaken and carried out by a contractor.

When a syndical association carries the work into execution, its statutes usually determine on what lines the distribution of water shall be regulated. But when the works are taken in hand by a contractor, the distribution is fixed, either by a decree published after the council of state has recorded its decision, or by a decree signed by the prefect or chief magistrate of the department in which the works have been, or are to be, executed. The prefect is empowered to sign these decrees since August, 1886.

The syndical associations are composed of land-owners whose interests are affected by the want of irrigation. Their powers, privileges, etc., are more or less determined by common law.

The French Senate is at present discussing a projected rural code, which will contain a certain number of articles relative to irrigation.

In a general way the quantity of water required to irrigate a hectare is equal to an outflow of one liter per second all the year round. The cost per hectare is apt to vary considerably if the works are executed by a syndical association. In that case the average cost may be set down at 40 francs per annum for a supply of water equal to about 1 liter per second. If, on the contrary, the works are carried out by a contract, the cost is always a fixed one, it can never vary, inasmuch as it has been determined by the deed of concession.

The following table shows the figures of the tax raised for some of the leading irrigating canals:

Canals.	Departments.	Cost.	
		A.	B.
		Francs.	*Francs.*
Pierrelatte	Drôme, Vaucluse	50	60
Bronne	Drôme	50	60
Visubie	Alpes Maritimes	80	....
Verdun	Bouches-du-Rhône	70	....
Saint-Martory	Haute Garonne	35	50

When two figures are given for a single canal the figures in column A show the tax due by the land-owners who subscribed before the water of the principal canal (see Answer 3) was turned into its destined channel, while the figures in column B denote the amount paid by those who subscribed afterwards. In the case of the last-mentioned canal, the figures shown in column A, the sum paid by land-owners who subscribed before the deed of concession was promulgated, and in column B the amount paid by those who subscribed after its promulgation.

Springs only may be owned either by private individuals, by the state, or by the small districts called communes.

Running waters are considered *res nullius*, but the use of them is regulated according to law on the non-navigable water-courses.

The water of navigable water-courses is considered national property.

(5) Character of climate in irrigated region, and nature of soil, annual rain-fall, and other precipitation.

Although the practice of irrigating is as widely spread in the north as in the south of France, it is chiefly in the regions bordering on the Mediterranean, where the summer rains often fail, the most important irrigating canals have been cut. In the north, east, or west the works designed to promote irrigation are nearly always carried out by private individuals. This is especially the case in the department of the Vosges. In the south they are, for the most part, the result of the combined efforts of a certain number of individuals. They are mainly undertaken where the soil is of a chalky nature and in lands formed by alluvium.

Among the systems adopted to distribute the water may be mentioned an interesting one practiced in the department of the Bouchesdu Rhône. It is a kind of irrigation by submersion. The lands subjected to this method are constantly increasing in extent.

The land owners whose properties are situated on the banks of the Rhône obtain, when they require it, and by means of elevating machines, the quantity of water necessary for the process of submersion, which lasts sixty days and consumes not fewer than 1,500 cubic meters per hectare. The estates in the center of the island of Camargue, in the same department, are less favored than those seated on the river banks. The water has to be conveyed to them from the river by means of small canals and side channels, which generally belong to syndical associations of a very remote origin.. These side channels work during the rising of the Rhône. As, however, the frame-work of their flood-gates is almost on the same level as the low-water mark of the river, when it is not higher, it often happens that, when the Rhône is low, the side channels become dry. Besides this, the season for submerging the land often coincides with this autumnal fall of the river, and irrigation is practically brought to a standstill.

Numerous plans have been formed to find these side channels by means of large canals cut in the north of the island. But none of them have yet been carried out. Pending the execution of a plan a society of land-owners, headed by the Count of Chevigne, recently set an example well worth following. Their project is not less remarkable for the way in which it was conceived than from the results which may be expected from it. They are thirteen in number, and their combined estates contain some 1,500 hectares. In order to keep their side channels constantly supplied with water they applied to several mechanical engineers for machines, and finally adopted an apparatus presented by one of them, and which has given the most satisfactory results.

Its characteristic feature is that instead of being a fixture it floats and can be conveyed from one place to another. Thus it can be made to work anywhere. It consists of a boat built wholly of iron, and equally adapted to fluvial and maritime navigation. Its length is 24 meters; its breadth 5 meters; and its draught of water nearly 1½ meters. It carries three engines on the compound system in juxtaposition, and of 200 horse-power. Two of them each turns a rotary pump by bearing directly on its beam. The third, which can be made to work either of the two pumps, is used only when one of the other engines is out of order. On the one hand, these machines are condensing engines; on the other, their steam is provided by boilers on the Bigot system. These latter are used in the French Navy, and possess a collective warming surface of 80 square meters. Their consumption of fuel is therefore comparatively small. The pumps fixed up on board are on the Decœur system. They raise the water from a depth varying between 1½ and 2½ meters, according to the level of the Rhône, and distribute the water at the rate of from 750 to 1,500 liters per second.

The following table gives more ample particulars. To understand its figures rightly it is necessary to know beforehand that they are given when both engines are working together and distributing 500 liters per second:

Height above river.	Horse-power.			Number of turns.	Consumption.	
	In quantity of water brought up.	On the beam of the pump.	On the sucker.		Total per hour.	Per horse-power of water brought up.
Meters.						
1.00	15.0	24	32	140	35.20	2.340
1.50	22.5	36	48	160	46.86	2.348
2.00	30.0	48	64	160	70.40	2.340
2.50	37.5	60	80	170	88.00	2.340

When the pumps distribute 1,500 liters instead of 500, these figures remain proportionately the same. The suction is performed in a special division provided with vases, and the water is thrust back into a collecting pipe which serves for both engines at the same time the boat is working; it is moored on the spot from which the water is drawn up. The collecting pipe has a weir provided with a slat spout. It runs into a sheet-iron reservoir placed at the head of the side channel and outside the river dam. The connecting of the weir with the collecting-pipe is accomplished by means of a link with a hinge to it which enables the spout to remain constantly in position on the edge of the reservoir, whatever the motion of the boat may be. By this arrangement the work done by the pumps is limited to a height corresponding with the difference in the level of the water, and with that fixed for submerging the land. This second level is slightly below the height of the reservoir itself.

The annual rain-fall for all France is estimated at about 77 centimeters.

(6) Antiquity or otherwise of irrigation systems within the section treated of, and whether the same are maintained at public or private expense?

The cutting of a certain number of canals for irrigation in the southern districts dates from several centuries. The more important works, however, are of comparatively recent origin. During the last ten years, especially, a great impulse has been given to the construction of works devoted to irrigation. Subjoined is a list of the most notable enterprises of this kind. It is taken from the "Journal d'Agriculture pratique."

Departments.	Description of works.	Cost. *Francs.*
Drôme	Canal de la Bronne	13,000,000
Alpes-Maritimes	Canal de la Vésubie	7,000,000
Aude and Hérault	Canal to be used for submerging both departments	2,400,000
Duôme and Vaucluse	Canal de Pierrelatte	8,000,000
Basses-Alpes	Canal de Tranasque	4,500,000
Hautes-Alpes	Canal de Ventaron	2,000,000
Aude	Canal de Canef	1,000,000
Bouches-du-Rhône	Drying up the Fos Marshes and purifying the waters of the Cran.	18,000,000
Hérault	Canal de Gignac	4,200,000
Loire	Canal de Farey	7,000,000
Alpas-Maritimes	Canal de Toulon	1,200,000
Aude	Canal de Cuxac	2,000,000
Do	Canal de Suc	} 1,160,000
Do	Canal de Fabrezarn	

The public treasury generally contributes one-third of the costs of the works; the land-owners interested in them defray the remaining two-thirds. In the case of the most important works, the state, besides contributing its third, has guarantied for the space of fifty years, to the parties who covered the loans raised for the purpose of carrying out the works, the interest due on the sums lent to the contractors.

TRANSLATION BY UNITED STATES CONSUL DUFAIS, OF HAVRE, OF A LETTER ON IRRIGATION FROM MR. LUCIAN, CHIEF ENGINEER OF ROADS AND BRIDGES, DEPARTMENT OF CALVADOS, FRANCE.

CAEN, *August* 30, 1889.

SIR: I beg to answer in the following order the several questions asked in your letter of the 8th instant:

(1) Calvados being a cattle-raising country since a long time, the utmost has been done to utilize the water. The new demands for irrigation are therefore very rare, and it is to be supposed that the surface of the irrigable lands is already under irrigation. This surface, according to a statement made in 1870, was only 1,372 hectares (3,390 acres). This small proportion of the surface of the department which contains 552,000 hectares (1,364,544 acres) is explained by the dampness of the climate, which rather needs being made salubrious by drainage of marshes, etc., than by irrigation.

It is important to note that nearly 20,000 hectares (49,440 acres) are irregularly watered by flood or wild waters.

Artificial irrigation is exclusively applied to permanent meadows.

(2) The water used for irrigation comes exclusively from the streams.

(3) The works constructed on streams for the distribution of the waters used for irrigation generally consist of bars fitted with water-gates able to be lifted above the highest water. These bars are authorized by a prefectoral commission prescribing the dimensions and dispositions. Moreover, everybody may after an administrative inquiry obtain the authorization of using a stream of which he is a borderer, said water, after he has used it, to be returned to its natural course, under all reserves, however, of the rights of third parties.

(4) Nearly all irrigations in Calvados are of a private character; there are none of a collective use to report but two.

Irrigation of the small valley of Aute (arrondissement of Falaise). A decree dated February 11, 1881, rendered after inquiry, has authorized and located the establishment of 16 bars constructed in the River Aute. A prefectoral decree settled the dates and hours of irrigation for each bar. The surface of the land to be watered is 152 hectares (376 acres).

Irrigation of the valley of Orber within the limits of the department at Lisecua. It is not a question in fact of irrigation exclusively. The land proprietors joined in a syndical association to secure on one hand the irrigation of 286 hectares (707 acres) of meadows, and on the other the working of the numerous factories situated in an industrious valley, where there are at least 85 streams and brooks. This syndicate is regulated by a decree dated June 18, 1864, which stipulates the use of the waters and settled the dates and hours of using the water, always considering the wants of the factories.

A syndical commission, whose members are appointed by the prefect (according to the statutes), manage gratuitously the interests of the association, the expenses, etc., by means of a roll rendered executory by the prefect and which is collected by the "receiver of finance" of the district, commissioned to that effect. By means of this roll the expenses are apportioned between the interested land-owners in proportion to the value of their property. There are no fees for the use of the waters, which are common property of the adjoining landlords.

The syndical associations established previous to 1865 are under the rules of the law dated June 21, 1885, modified by the recent law dated December 22, 1888.

(5) Climate damp; the yearly average rain-fall is 700 millimeters (27½ inches).

Calvados soil, heaths and waste lands, 12,000 hectares (29,664 acres); rich soil, 150,000 hectares (370,800 acres); calcareous soil, 150,000 hectares (370,800 acres); gravel soil, 8,500 hectares (21,212 acres); stony soil, 5,000 hectares (12,360 acres); sandy soil, 2,500 hectares (6,180 acres); marshy soil, 70,500 hectares (174,276 acres); diverse soils, 173,300 hectares (429,092 acres).

The most part of these soils is divided as regards agricultural purposes in 317,000 hectares (783,624 acres) arable lands, and 141,000 hectares (348,550 acres) of natural and artificial meadows.

REPORT OF CHARLES B. TRAIL, U. S. CONSUL, MARSEILLES, ON IRRIGATION IN THE DEPARTMENT DES BOUCHES DU RHONE.

Metric denominations and their equivalents:

Meter equals 39.37 inches.
Hectare equals 2.471 acres.
Liter equals .908 quart, dry measure.
Liter equals 1.056 quart, liquid measure.
Hectoliter equals 2 bushels, 3.35 pecks, dry measure.
Hectoliter equals 26.44 gallons, liquid measure.

Much attention has been given to irrigation in France during the past century, and the Government has from time to time sought to increase the public interest in this most important subject by publishing scientific reports on the same, and, more recently, by instituting "concours" and offering prizes to those adopting the best methods and securing the best results from irrigation. In the north of France irrigation is accomplished by simply inundating the land, and is confined principally to submerging meadow lands in the autumn by turning off large quantities of water from the rivers and streams; in the central portion, by the use of water from springs and wells distributed over the land by hand and machinery; and in the south province, the Department des Bouches du Rhone and its neighbors, by irrigating canals.

Irrigating canals of any importance are confined to the valley of the Rhône, the foot of the Pyrénées, and to only a few other localities in France. The canals of northern and central France are only used for transportation.

Given sufficient water there is no reason why a canal should not serve for both transportation and irrigation. This is done in Italy with the addition of obtaining motive power from the current as well; but in France the canals only fulfill one function at a time with but a few exceptions.

The use of canals for irrigation is of very ancient date in France. The first canal in Provence that we know of was constructed by Marius, the consul, in 103 B. C., for the purpose of transporting supplies to the Roman army, then encamped near Arles, and it is probable that it afterwards, when abandoned as a water-way, served to irrigate the land contiguous with it. Arthur Young, traveling through Provence towards the close of the last century, was particularly interested in the irrigating canals he there saw, and expressed his surprise that other parts of France did not imitate the Midi in this most important of rural economies.

Irrigation of some sort is indispensable in the Midi. Without its aid agriculture would have to be abandoned. Three months and occasionally nine pass by without rain-fall. The summers are long and the heat great and continuous, while the sun shines through an intensely pure air, unobscured by a single cloud, subjecting the land day after day to a constant drying and scorching process and causing every particle of humidity to evaporate.

The department des Bouches-du-Rhône, to which the report is limited, forms the southeast of France bordering on the Mediterranean and, as its name implies, comprises the territory surrounding the mouth of the Rhône. Its northern boundary is the river Durance, which, rising in the Alps, flows westwardly and empties into the Rhône not far below Avignon.

From the Durance the irrigating canals are principally drawn. The area of the department is 510,487 hectares. The entire surface artificially watered embraces 35,091 hectares, and of this the Durance contributes water for 26,880 hectares, or—

	Hectares.
Irrigation from the Durance	26,880
Irrigation from Huveaune, Arc, La Touboulu, etc	2,911
Irrigation from the Rhône	5,300
	35,091

A glance at the map on page 12 of the "Rapport sur la Concours ouvert en 1875," accompanying this report, explains why it is that the Durance has been so heavily tapped to supply irrigation for this department.

Provence is composed of mountains, hills, and plains. The greater part of the soil is naturally very poor, it being detritus brought down from the Alps by the Durance, and in flood-time spread over the plains. Strong winds sweep over it at times. The soil naturally produces only stunted trees and coarse grasses; but by irrigation and the liberal use of manure a maximum of fertility is obtained where from the want of water absolute sterility reigned.

Geographically speaking, the department des Bouches-du-Rhône presents three distinct features. First. A mountainous section to the north and east, composed almost entirely of limestone of a dull gray color and in part quite naked of vegetation, and in part covered with wood. Streams from the mountains descend to the Durance, to the Rhône, and to the Mediterranean. Second. Two plains, la Crau in the center of the department, very stony, and la Camarque to the west, composed of mud and sand. Third. Marshes and ponds, shallow reservoirs, whose waters flow slowly to the sea.

There was an old French proverb that said Provence had three curses to contend with: Parliament, the river Durance, and the mistral. Parliament was swept away by the revolution. The Durance, whose waters at times overflowed its lands and carried destruction in their wake, has been tamed by man's ingenuity and from a curse its waters have become a blessing; whilst the mistral, the northwest wind, the great drawback to life in Marseilles, and in all Provence, that at times sweeps with terrible force over the country up-rooting trees and destroying buildings, has, owing to the greatly increased humidity of the atmosphere, caused by the irrigations from the Durance, lost much of its former force, is less frequent, and of shorter duration. It is supposed that the mountains here were once covered with timber, the rain-fall regular, and the land fertile; but their denudation of timber deprived the country of a storage for humidity; the rain-fall becoming irregular caused the volume of water in the streams to vary greatly, mountain detritus was spread over the formerly fertile plains; the heat and duration of summer became greatly augmented, and the hot air arising from the parched arid earth originated the mistral.

There are five groups of mountains and they take up three-quarters of the department. The topography in this section is the most varied, the mass being twisted into peaks and chains, between which lie valleys, lakes, and ponds. The plains la Crau and la Camarque take up the remaining superficies of the department. They incline slightly towards the sea and the large rivers. La Crau, comprising 35,000 hectares, of which 15,000 are cultivated and irrigated (1875), is formed mainly of pebbles brought down from the Alps in the glacial period. Before the construction of the canal de Craponne la Crau was one vast uncultivated tract, affording but a scant and coarse pasturage enjoyed in common by the inhabitants. Since the coming of the canal this region has been metamorphosed; rich farms spread over what was once but a desert. La Camarque is that vast delta comprised between the two great branches that the Rhône divides itself into before entering the sea.

It keeps growing constantly from the additions made to it by the deposit of matter carried down by the river in suspension. In area it is 88,300 hectares; 50,000 are wild, uncultivated pasturage, and 23,000 marshes and ponds, and 15,300 under cultivation. There are several canals in this section, but the figures above show how much remains to be done. The history of the formation of this plain by the river dates back to 400 B. C. From statistics of 1855 it appears that of the whole area of the department about 7 per cent. is water.

	Hectares.
Ponds and irrigating canals	
Transportation canals	456.75
Lagoons	44.38
Rivers, lakes, streams	11,565.34
	23,270.64
Total water area	35,337.11

Considerable tracts of land formerly under water have been reclaimed. In some cases a canal for drawing off the water from swamps and marshes has also been used for irrigation. These reclaimed lands when properly drained and watered have proved fertile enough to pay handsomely those who had the foresight to plan and execute the necessary work.

When we come to examine into the quantity and quality of crops grown and the increase in and of the same due to irrigation, we are met with the difficulty of statistics that are conflicting and at times irreconcilable.

Even in the extent of the department we find—

Area of department statistics of—	Hectares.
1864	
1867	512,232
1870	496,464
	510,487

a difference for which no explanation is given.

A table of agricultural statistics was prepared by M. Villeneuve in 1820 and one by the Government in 1870, which are taken as reliable. It will be seen that both these tables make the departmental area about the same. In 1820 the cultivated land was 169,000 hectares to 341,000 hectares uncultivated, or as 1 is to 2; while in 1870, if we add the woods to the uncultivated, we have: Cultivated, 201,000 hectares; uncultivated, 309,000, or as 2 is to 3, instead of as 1 is to 2, in 1820; a gain of 32,000 hectares of cultivated land in fifty years, or about 19 per cent. Here are the tables:

1820.

	Hectares.	
Cultivated:		
Arable land		
Meadows	105,000	
Vineyards	16,000	
Olives	20,000

Roads, water courses, and uncultivated lands	59,587	
		218,247
Total area		510,487

According to the Government report of 1875 it appears that this increase of 32,000 hectares of cultivated land in fifty years was due solely to irrigation, there being about that much more land irrigated in 1870 than there was in 1820.

Statistics in France are not obtainable for periods of more than fifteen or twenty years at a time, then a break of a year or two occurs caused by a revolution and a change in the form of government, so that we have no statistics covering very long periods, we have them only in sections.

Taking up the agricultural products somewhat in detail and making a comparison of certain years as obtained from statistics, we have for cereals in 1840, 70,312 hectares devoted to their culture, and after a period of thirty-two years, 1872, 82,223 hectares employed in the same culture.

Wheat shows an increase of over 30 per cent.; oats remain about the same; rye, which in 1840 was 2,711, in 1872 falls to 380; barley, in 1840, 4,211, to 2,507 in 1872; corn, in 1840, 56, to 30 in 1872, the tables showing an increase in area sown in cereals of 16½ per cent. in thirty-two years.

1840.

* Approximated.

† Woods and forests belong to the department, to public establishments, to commerce, and to individual owners.

The increased area devoted to wheat was obtained from cultivating waste land. From 1820 to 1839, 65,000 hectares were anually sown in cereals; from 1840 to 1859, a mean annual of 76,000; from 1860 to 1874, a mean annual acreage of over 78,000.

As to the yield of wheat per hectare, it varies not only on different farms, but on the same farm in different years. A good year returns about 15 hectoliters to the hectare, or about 16⅔ bushels to the acre. In 1868 the yield per hectare was only 8.05 hectoliters, or about 9 bushels to the acre. The wheat, winter wheat almost exclusively, is sown two consecutive years on the same land, which is then given a year's rest.

Of fallow land—arable land permitted to lie idle—there was in the department in 1840 60,000 hectares; in 1852 this had fallen to 29,000, and since 1862 to less than 23,000.

The jury who examined the irrigated farms in 1875 and awarded the prizes* state in the "rapport" that the disappearance of idle land is due to irrigation.

---

* The prizes referred to were offered by the French Government in 1875 to encourage the advancement of agriculture by irrigation. First prize, farms of over 4 hectares showing best results from irrigation, a gold medal and 1,000 francs; second, 700 francs; third, 600 francs.

For farms of less than 4 hectares: First prize, gold medal and 600 francs; second, 500 francs; third, 300 francs. A silver medal accompanied the second prizes and a bronze one the third. It was intended that the "concours" should last for five years, but it seems that it was given up after two years. The first year thirty-nine farmers contended for the prizes, and the jury who visited their farms made a brief report on each one; their report is to be found in the "rapport" for 1875 that accompanies this brief investigation.

The statistics for the cereals, 1860 to 1874, fifteen years referred to above, are:

Year.	Areas sown with— Wheat.	Rye.	Barley.	Maize.	Oats.	Total of cereals.

* No statistics by reason of the war.

The other more important products of the department are: Potatoes; vegetables, dried and fresh; the olive, vine, fruits, and tobacco. In their cultivation arrosage from the canals is being used more and more every year, as will appear later on.

For potatoes we have:

	Hectares.
1840	2,415
1852	3,446
1871	6,569
1872	5,729

No statistics as to yield per hectare.

For dried vegetables, beans, peas, lentils:

	Hectares.
1840	2,207
1852	2,608
1862	3,407
1871	3,509
1872	3,650

Fresh vegetables, market gardening, in 1862, 4,117 hectares. Since that time the raising of "primeurs" for the London, Paris, and Marseilles markets has greatly increased, so that the acreage now given to fresh vegetables exceeds 6,000 hectares.

The olive fell off from 24,000 hectares in 1840 to half that figure in 1872. This was caused by the large importation of Italian olive-oil and also to serious losses sustained by the French olive farmers, due to a succession of heavy frosts.

The vine has experienced many vicissitudes and shows great fluctuation.

	Hectares.
1840	24,991
1855	44,069
1869	61,303
1872	28,897

The old method of sowing wheat, etc., in the spaces, 1 to 2 meters between the rows of vines, is now regarded as very bad farming, neither harvest being up to the full yield, and the land is rapidly impoverished by the double work exacted of it. In 1866 a new enemy of the vine made its appearance in Vaucluse, and from thence gradually spread over the greater part of France, threatening the total destruction of viniculture. This was the phylloxera, a microscopically small bug, prodigiously fecund, multiplying itself by myriads on the roots of the affected vines, and exhausting the sap until the plant died. This insect after destroying one vineyard migrates to the next to continue its work. Various expedients were tried to kill the enemy, the object being to find some substance that, mixed with the earth, would destroy the insect without injury to the vine; but these efforts were not crowned with complete success.

A viticulteur, M. Francon, of the Bouches du Rhône, conceived the idea of drowning the pest, and it now appears that if the afflicted vines are submerged under water for a sufficiently long time they are completely freed from it. M. Francon submerged his vines for thirty consecutive days immediately after the vintage and killed the phylloxera without injuring the vine. The quantity of water necessary to submerge a vineyard depends on the permeability of the soil. About 864 cubic meters of water every twenty-four hours for each hectare was sufficient in M. Francon's case. The earth must be completely saturated to the depth of the roots. The submersion being accomplished the vines should be pruned and manured. This, of course, in the autumn after the vintage.

Among fruits the almond has been increasing in favor steadily since 1860. From 1,500 hectares in 1860 the number went up to 7,000 in 1870.

Other plantations of less extent and importance are: Figs, capers, jujube, pistache, peach, apple, pears, cherries, apricots, pomegranates, medlars, quinces, walnut, prunes, and agerole.

Much greater care and study is required for irrigating with good results the larger fruit trees than is necessary with the cereals and vegetables.

In 1863 there were seven hundred and fifty-two farmers, who raised 183,500 kilos of tobacco on 124 hectares, which the Government report of 1875 says paid them 945 francs per hectare, or about $90 per acre. In 1875 there were only two hundred and sixty-five farmers raising tobacco on 43 hectares. These are the last statistics. Now as to cost of production. Heavy manuring and frequent arrosage are required. The decline in tobacco production is partly explained by Government interference. A special permit must be obtained to raise it, and the Government specifies the kind of tobacco to be grown. It can be sold only to certain firms and at a fixed price. Its production in this department is unimportant.

One is led to compare southern California with Provence. The first has a milder average climate and a richer soil, enabling it to produce even a greater variety of fruit, in addition to the cereals, than southern France. It is stated that the counties of Los Angeles, Santa Barbara, Ventura, San Bernardino, and San Diego are alone capable of producing all the figs, grapes, olives, oranges, lemons, nuts, and prunes imported from France, Spain, and Italy. When land there is improved with bearing vines and fruit trees it brings from $100 to $500 per acre, while unimproved land can be had for one-fifth that price. Unimproved land in southern France means non-irrigable land, and can be had for $15 per acre, while lands of identically the same soil that are irrigated (*qui sont arrosés*), bring $500 per acre, devoted to the olive, small fruits, etc. These are the land values given by M. Menestrel in 1822, and it seems they are about the same to-day.

Southern California presents a similar climate, better soil, doing away with or greatly lessening the use of manure, one of the heaviest items in French farming, and needing but one thing—irrigation—to make the whole country as productive as the very choicest sections now are and capable of supporting an immense population. The most important question for southern California is irrigation, a rural economy that has been studied and successfuly practiced here for centuries.

While the cereals seem to be suited to large farming (*la grande culture*,) the vine, olive, small fruits, etc., pay better when produced on a small scale (*la petite culture*).

Southern California should be divided up into thousands of small fruit farms. French properties of this sort are frequently not more than 20 acres, sometimes much less, that being all the land one average family can cultivate without the employment of hired labor. The products of such a farm are raised on small patches.

One frequently sees but one acre given to wheat, another to the vine or olive, several for gardening, and the remainder in pasture on a 10 or 15 acre farm. The diversity of production prevents the farm work from being over-exacting at any one period, enabling the family to work on the different crops at different times, and keeping it busy all the year round. Besides it is found, even on these small farms, marked differences in the soil occur, so that experience has taught that it is more profitable to divide up 10 acres in several cultures than to confine them to but one. These small farms require little or no machinery in the American sense of the word.

Southern California should be covered with a net-work of irrigating canals as is the Bouches du Rhône. It appears that the Santa Anna is tapped to such an extent that in summer the river bed is perfectly dry and the irrigating value of its waters quite limited. By the construction of reservoirs for the storage of the waters that are allowed to escape to the sea in winter the irrigable area can be increased to any desired extent.

It is interesting to note that just as the water supply for arrosage in the Midi was and is managed by companies, so we read in the San Bernardino Times that "the Ontario Land Company has driven a tunnel in under San Antonio Creek a distance of nearly 1,800 feet at a cost of about $52,000, and they have about 250 inches of water, worth $250,000.

Part II. Irrigating canals, their origin and management, will be forwarded as soon as certain statistics can be obtained.

REPORT FROM F. F. DUFAIR, U. S. CONSUL, HAVRE.

[WITH INCLOSURES ON IRRIGATION IN THE DEPARTMENTS OF MANCHE, ILLE-ET-VILAINE, AND MAYENNE.]

This service (irrigation) is under the immediate management of the chief engineer of ponts et e chaussés (roads and bridges) in each department of France and under the head control of the chief engineer, director of agricultural hydraulics, Mr. Philippe, of the ministry of agriculture, at Paris.

The fact that Mr. Quinette de Rochemont, the head engineer of the port of Havre, has been absent for some weeks, the only government officer who could give me the desired information, must plead my excuse for not reporting before this.

From him I learned that there is no system of irrigation in the arrondissements of Havre and Yvetot, in the department of the Seine-Inférieure; the remainder of this department is under the management of Mr. Vivenot, chief engineer at Rouen. The chief engineers of the departments in my consular district, besides the above named, are Mr. Lucau, at Caen, Calvados; Mr. Perrin, at Alençon, Orne; A. Gouton, Cherbourg, Manche; L. Rousseau, Rennes, Ille-et-Vilaine; Floueand de Fourzcroy, Laval, Mayenne, to whom I addressed myself for the required information, and, with the exception of the two first named, they very obligingly answered my questions by the letters herewith inclosed, accompanied with my translation.

[Translation.]

LETTER OF A. GOUTON, CHIEF ENGINEER OF ROADS AND BRIDGES OF THE DEPARTMENT LA MANCHE.

CHERBOURG, *August* 17, 1889.

In answer to the request for information which you were pleased to address to me on the 8th of this month, I have the honor to say that there is very little irrigation, properly called, practiced in this department for summer watering. On the contrary, the climate, which is a most temperate one, makes submersions of low meadows during the winter months by means of brackish water very useful.

With these general remarks permit me to sum up the answers to questions 1 to 6 as follows:

(1) I have no data as to the extent of irrigable compared with non-irrigable or cultivated land in the department. It consists of pasture land for grazing cattle, or of meadows furnishing mowed hay.

The quality of this pasturage is most excellent, such as that of Isigny, Bessin (neighborhood of Bayen), Carentan (or, properly called, Cotentin), Valognes, etc., producing the famous butter of Isigny and Cotentin, the best in France.

(2) The water producing this rich grass in the department of Manche is almost exclusively rain-water. Rains are very frequent but rarely stormy or chilling, and

the average annual rain-fall at Cherbourg or Isigny reaches from 1 to 1.10 meter (39⅜ to 42 inches).

There are numerous springs, brooks, and streams, but it is only in the winter time, with rare exceptions, that lands are being overflowed.

(3) Therefore there are no reservoirs, only simple trenches, for the distribution of the water on irrigated meadows.

(4) The usage of water for irrigation is regulated by common law (articles 643, 644, 645, code civil) and the laws of April 29, 1845, and July 11, 1847.

Besides that, work of irrigation occasions syndical associations, subject to the law of June 21, 1865.

(5) The climate of the soil is most variable in the department of Manche, presenting the greatest variety of geological formations next to tillable soil.

(6) The local habit of submerging lands in the winter months in sweet water is very ancient; it is principally practiced on meadows and pastures near the sea, where the soil is below the level of high tides.

Winter irrigation in other regions of the department is in the hands of individuals without either rules or co-operation.

The general service of the water-courses, useful as well as detrimental to agriculture, devolves upon the department of ponts et chaussées (roads and bridges), having charge of agricultural hydraulics and belonging to the minister of agriculture.

[Translation.]

LETTER OF LÉON ROUSSEAU, CHIEF ENGINEER OF THE DEPARTMENT OF ILLE-ET-VILAINE.

RENNES, *August* 14, 1889.

SIR: Irrigation in the Department of Ille-et-Vilaine is of very small importance. Here is in a few words my report to the minister of agriculture:

Regular irrigation, that is to say, such as permits the possibility to admit and to draw off again the waters according to the requirements of cultivation at the proper time, is extremely rare.

One single instance of this kind has been submitted to the engineers in 1888 concerning the brook Français, on the confines of the departments of Ille-et-Vilaine and Manche.

Elsewhere irrigation consists only in submersion, in consequence of the rise of brooks, of natural meadows situated in the bottom of their valleys. The receding of the waters into their beds after freshets is facilitated by a great number of trenches dug at the confines of the several parcels of fields or traced according to the depressions of the soil.

Submersions are also practiced in some dried up ponds which have been transformed into meadows. These ponds having been drained by breaching a dike or highway to allow the water to run off, the system of irrigation consists in temporarily stopping up such breach to allow the water to rise and to overflow the neighboring fields.

LÉON ROUSSEAU,
Chief Engineer of Road and Bridges, Ille-et-Vilaine.

[Translation.]

LETTER OF MR. FLOUAND DE FOUZEROY, CHIEF ENGINEER OF ROAD AND BRIDGES, DEPARTMENT OF MAYENNE.

LAVAL, *August* 10, 1889.

SIR: You are pleased to send me an interrogatory regarding irrigation.

I should have been happy to answer it, as far as this department is concerned, but it would be difficult to do so in a precise manner.

Irrigation is frequent in this department, where the soil is very much broken and divided into a great many basins; there are thus many small and rapid water-courses, where it is easy to construct small dams and to turn the water into trenches to irrigate numerous natural meadows; but there are no statistics existing to state the extent of land susceptible of irrigation compared with such as is non-susceptible.

There are no reservoirs; there is only one syndical association of small importance occupying itself, principally, with the draining of meadows with the view of making them salubrious.

The climate is rather rainy, the subsoil impervious; there are no extended or deep valleys, neither are there table-lands or heaths.

On the whole I don't believe that the interrogatory which you did me the honor of addressing to me can be answered in an interesting or precise manner.

Please accept, etc.

FLOUAND DE FOUZEROY.

REPORT FROM ALBERT N. HATHAWAY, U. S. CONSUL, NICE, ON IRRIGATION IN SOUTHERN FRANCE.

Irrigation here is applied for the most part to ornamental, horticultural, and vegetable gardens, instead of to fields of general agriculture, and to no grain lands whatever, and in but small extent to the vineyards and orchards of oranges, lemon, and olive. The expense for flowage water, procured from the hydrants works of the city of Nice, renders such use largely unprofitable, and the scarcity of the natural supply precludes its systematic application to any wide degree, except in the valleys of the Var and lesser rivers. When irrigation here is practiced production is doubled without injury to the quality of the crop; sterile soils, long useless, recover and yield abundantly, and in many localities, to insure valuable returns to the husbandman, it is of absolute necessity.

The ordinary sources of water, for the purpose, are ancient wells from which, during hours in each day, it is drawn by mule-power and quite primitive machinery into distributing tanks and inherited slow methods of labor.

The said company having obtained a concession, with an appropriation therewith of two and one-half millions from the state, was organized in 1878 and its works established at a cost of 12,000,000 francs.

Its supply is obtained from the river Vesubie, in the valley of that name, distant about 30 miles from Nice, from which river it is led, flowing at the rate of 4,000 liters each second, in an open, cemented canal to a distributing reservoir on the heights in the suburbs of said city. In its treaty with Nice the company is bound to supply the city, for the annual payment of 80,000 francs, with 60,000 cubic meters of water daily for its abattoirs, sewers, fountains, and public works. The water for domestic uses, also provided by said company, is derived from a separate source, viz, the mountain springs of Sainte Thecle. Under the aforesaid concession from the state the company covenants, during the term thereof, viz, until 1972, to maintain the construction of their works for the public utility of the region and to furnish flowage at fixed prices therein stipulated. Otherwise than this, said corporation is unsubjected generally to the Government control. The established tariff for its continued use for irrigation on ordinary levels is as follows, viz: For 1 cubic liter per day, annually, 30 francs; for 2 cubic liters per day, annually, 55 francs; for 3 cubic liters per day, annually, 60 francs, and for each additional daily cubic liter, 20 francs annually. The tariff for its periodical use is proportionate to the above table, conditioned, however, to an agreement as to quantity to be consumed. The service pipes are in all cases at the charge of the proprietor.

The region, having thus facilities of irrigation, is by nature restricted to the foot-hills and narrow valleys of this district, beyond and above which are the mountains barren of or discouraging to cultivation. The limits, owing to the configuration of the coast, the counter scarps of Alps, and the proximity of the sea, which serves as a vast reflector of the sunbeams, is semi-tropical in character. The soil, producing two or more variable crops a year, is alluvial, with a humus surface and a gravelly substratum, and quickly absorbs all moisture. In May the temperature averages 64°, in June 70°, and in July and August 78° Fah. In winter it averages 52°. From May to November more than one hundred days are usually without clouds. The average rain-fall is from 80 to 100 centimeters per annum.

REPORT FROM EDWARD CAMPHAUSEN, U. S. CONSUL, NAPLES, ON IRRIGATION IN SOUTHERN ITALY.

I have the honor to report that on receipt of your circular instructing me to furnish information on the subject of irrigation as practiced in this country, I immediately applied for statistics to the prefect of the ten provinces composing this consular district.

In course of time, after the delay usual to these officials, they replied that, owing to the scarcity of water-courses, there were no lands under irrigation in their respective provinces. It is claimed that the geological and lithological condition of the country are such that it would be impossible to carry any system of irrigation into effect.

This country depends absolutely on the rain falling mainly during the months from November to April. The average annual rain-fall is said to be about 20 inches. There are some lands under private irrigation. The water supply belonging to the respective land-owners is taken from wells, at a depth varying from 25 to 100 feet, water being found in abundance at that depth in most parts of the country. Near the coast of the Adriatic and Mediterranean wells are formed by the infiltration of salt water. Some of these belong to communities, but no definite law or regulations appear to exist for the use or distribution of the water, and there is no irrigated land, in the true sense of the word, in this district.

I inclose a copy of the law concerning the derivation of public waters and also a publication discussing a project for supplying the province of Ban with water for domestic purposes.

REPORT FROM EDWARD P. EARLE, U. S. CONSUL, COGNAC, ON IRRIGATION IN THE DEPARTMENT OF LA CHARENTE.

I deferred answering the Department's circular of May 2, 1889, concerning the methods of irrigation in use in my consular district, until I could fully possess myself of the facts of the case. To this end I sent the circular, through Hon. Oscar Planat, the mayor of Cognac, to the chief engineer of La Charente, at Angoulême. I received from him a few days ago, through the mayor, a long, rambling reply to my interrogatories, which may be summed up as follows:

(1) That the engineer has no knowledge of any system of irrigation now in practical use in this department.

(2) That all his information is derived from the library and archives of his office, and finally that he refers me to the departments forming the old government of Provence. There, he says, extensive systems of irrigation are practiced. He also suggests that inquiries should be addressed to the minister of agriculture, at Paris.

For my own part here are my observations:

This part of France is quite abundantly watered; the Charente, the Nee, and many other smaller streams traverse it, and so far as my observation extends the question with farmers here is what to do with surplus water rather than any question of irrigation. All the canals, dikes, and ditches are exclusively for the purpose of restraining overflows or for draining wet or submerged lands. The river and creek bottoms are generally broad and level and very subject to overflow, to the great detriment of the grass planted thereon. The receding waters leave a fine deposit of mud on the stems and blades of the grass, which, drying with the hay, becomes a dust very damaging to the stock eating it. At this moment, when the new hay crop is come into market, almost all the horses of the arrondissement are affected with a severe cough like that of hay fever.

The highlands of this arrondissement are quite out of the reach, in my judgment, of any practicable system of irrigation, nor does it require it. Some seasons are said to be very dry, but a protracted drought I take it, is a rather rare occurrence. The principal characteristics of the climate appears to be its humidity. The night moistures or dews seem to me quite sufficient by themselves, the soil meanwhile being a little stirred to furnish all the plant requires.

I send no maps, published reports, or books on the subject of irrigation in France, as the consul at Marseilles, where that system of agriculture prevails, can make a more discriminating selection than I could here. I content myself with saying, in fine, that no system of irrigation prevails in my consular district. I do not know, nor have I been able to find, any competent expert on that subject.

REPORT FROM WALLACE S. JONES, U. S. CONSUL, MESSINA, ON IRRIGATION IN THE PROVINCE OF MESSINA, SICILY.

Irrigation in Sicily dates from the occupation of the island by the Mussulmen. They took possession of Palermo in 831, and gradually extended their sway. Ruins of the Emir's castles, agricultural terms still in use relating particularly to irrigation, and numerous African plants all testify to their former presence here. In the year 872 they first began the use of the "*noria*" (*senie*), raising well water into water towers (*giarraton*) or cisterns (*giabiat*), whence it was distributed by means of small ditches (*sajat*), and this is the system in general use to-day.

Irrigation did not attain the same development in this province as in that of Palermo for the reason that water veins are not as numerous here. Since 1850 the search for water has been steadily on the increase, due to new methods of reaching it (by drilling) and of raising it (by endless chains of iron buckets instead of the old-fashioned *noria* with paddles) and to improved gearing. Water is pumped up, and many of the wells are 100 feet deep and over, by horse-power; oxen are also much used for this work, and occasionally by steam-power. There is no coal in Sicily, and the lack of roads makes its transportation from the seashore too expensive.

According to the Italian civil code all waste under the beds of rivers or torrents belongs to the State; but while this is the law it happens, nevertheless, that owners of land along the water-courses use the water with more or less immensity, so that but a small quantity may be said actually to belong to the public domain.

The supply of water for irrigating purposes in this province is small. The extremely mountainous district of Val Demone is not adapted to the percolation of rain-water, particularly as a short-sighted policy has destroyed the natural reservoirs, the forests, thus permitting the rain to run off and waste. As a result not a single river is to be found in the province, but we meet at every hand destructive torrents (their beds are dry in summer), whose havoc is ever on the increase. There are no less than thirty torrents in a stretch of country 45 miles wide in this province. Natural springs are but few, so that the greater portion of the water used for irrigation as well as for drinking purposes is obtained by means of costly hydraulic works, tunnels, wells, cisterns.

The topography of the Messina district does not allow of the formation of lakes, and, with the exception of two small brackish sheets of water near the Faro and of a fresh-water pond in the commune of Rouella Valdemone, we find no lakes here.

Owing to the deficiency in the water supply and to the greater portion of this district being mountainous but one-sixteenth of the total cultivable area (*i. e.*, 14,000 hectares) is irrigated. Of the irrigated area:

	Hectares.
Oranges and lemons occupy	7,600
Market gardens*	800
Flax and hemp	200
Indian corn	1,000
Legumes (beans)	1,400
Fruit trees, peaches, pears, etc	500
Reed cane	2,000
Marshes	500
	14,000

Irrigated land produces crops not only superior as to quality but threefold as to quantity compared with non-irrigated land. Irrigated open land sells for three times as much as the non-irrigated; near the city of Messina it fetches from $780 to $1,230 per acre.

The water is pumped into well-cemented reservoirs or vats, generally prismatic in form (because cheaper), rarely circular. We also meet with covered cisterns. From the collecting reservoir the water is made to pass into the distributing reservoir through gutters called "condotti," or "tubi," conduits or pipes. The water is carried from the distributing reservoir to different parts of the grove, either by trenches called "sajat," or by brick conduits either closed or open on top. The latter are known as "brinzi."

The open conduits are to be preferred, because they do not choke and because they are not liable to burst.

Should the grove be extensive, small distributing reservoirs called "bisternoli" are established here and there.

This distributing of water for irrigation purposes, when the water is private property (for by law the owner is allowed to make what use of it he pleases, provided he does no damage to his neighbors), is not governed by law, but by special customs that vary with the locality and which it would be impossible to enumerate.

The cost of water for irrigation purposes is so complicated a matter that it can not be fixed precisely, but this much can be said: In this province a penna (a goose-quill) of water, *i. e.*, 36 gallons of water per hour, costs from $200 to $260 per annum.

Here, as a rule, water is private property. Some communes own water either by purchase from private parties or because its source is on community land.

The title to water is acquired by bargain and sale, exchange, gift, and can also be acquired by prescription. Not less than thirty years of undisturbed enjoyment are necessary to create title by prescription.

---

*It should be added that garden truck is very generally cultivated in the vacant spaces in orange and lemon groves.

As to the climate of this province, the maximum of heat is 87° Fah. Some winters the thermometer falls to 20° below freezing, but this temperature prevails for a very short period. Snow covers the tops of the mountains for several months during the winter, and nearly every year reaches the sea-shore, covering the ground for a few hours. At Messina the temperature changes with the currents (which are tidal) that pass through the straits. From October to December it rains frequently; in January and February it rains and snows; in March and April it rains constantly. Open weather begins in May and lasts to September with an occasional heavy down-pour. Annual rain-fall 22 inches. During the spring and autumn months fogs prevail on the mountains; it rarely hails; dew and white frost occur frequently; frost in April inflicts considerable damage.

No hydrographic maps or publications bearing upon irrigation in this province exist. Less attention has been paid to irrigation in Sicily than in any other portion of Italy; but little progress has been made since the days of the Arabs.

A few years ago a technical school for instruction in hydraulics was opened in Palermo. If the water of the numerous torrents in Sicily were to be controlled and utilized in irrigation, many localities now infested by pernicious and malarial fever would become healthy and habitable. Statistics show that one-fifth of this island is subject to the influence of stagnant water and of the dry beds of torrents during the summer and the organic matter accumulated for centuries in these low spots breeds foul emanations that poison the air.

No works for the storage and distribution of water have as yet been undertaken by the Government in Sicily. In 1858 a company with a capital of $150,000 undertook, under a charter from the Bourbon Government, to utilize the water of the River Simeto in irrigating a portion of the plain of Catania, the total area of which is 65,506 acres. A rough stone dam was thrown across the river at Paterno and two principal canals, one to the right (20,000 yards long) and the other to the left (30,000 yards long) of the river-bed were opened down to the ocean. Four secondary canals (leading from the principal canals) were also opened, and these were intersected by numerous irrigation ditches, the latter of a total length of 10,000 yards. The banks of the canals are faced with stone or with logs whenever the land has a tendency to slide. At the dam the canals are 6 feet wide at bottom, 29 feet wide at top, and 6 feet deep; the banks have an incline of 45 degrees.

The dimensions of the canals decrease as you go from the dam. The depth of water in main canals should never exceed 4½ feet. The average mean amount of water that passes through the canals is 722 gallons per second. The company charges $67 per 7 gallons a second from April to October 1, and $33.50 from October 1 to April 1.

In the plain of Catania, on a calcareo, argillaceous soil, wheat legumes and flax require 4¾ inches of water from October to April. Summer pasture lands require 12 inches of water. The very stiff clay lands in this plain appear to be adapted to rice culture only. Quite an area is so flat that the water ponds on the land and the slime left by the water impoverishes the land and makes it more difficult to cultivate. This undertaking has been a failure financially; not only has the original capital been sunk but a debt of $120,000 hangs over the company.

The only other work of importance in Sicily connected with irrigation is the dam 2½ miles above Ferranova, province of Caltanisetta.

This massive stone dam is 360 feet long, 24 feet wide at the base, 15 feet wide at the top, and 30 feet high, and was thrown across the River Gela at a cost of $85,000 by the wealthy Duke of Montelevore, descendant and heir of the great Cortes, as far back as the year 1788. An irrigation canal leads out from either wing of the dam; area irrigated 11,860 acres. Below the dam the water falls on a stone platform 138 feet wide by 123 long, and then follows its old bed to the sea. At the point where this dam is erected the river runs through a gorge, the sides of which constitute natural stone walls. An elliptical gap, 80 feet wide by 10 feet deep, has been left towards the middle of the dam. At this point fascines are thrown against the dam on the water side, and earth is thrown on the facines, constituting as it were a floating island, the surface of which is brought almost to a level with the dam on either side of it. Pistachio trees, tamarack shrubs, and grass are set to grow on this island, which serves as a tumbling dam.

As the water rises it gradually rus off, overflowing the island, which, in times of a strong freshet, is carried away bodily. It costs $500 per annum to keep up this island; it would cost $800 to replace it. The land irrigated by means of this dam produced from 1862 to 1865, 5,000 bales of cotton (of 450 pounds) per annum. Cotton is still grown for home wants on a small scale.

Since 1865, the Italian Government has expended large sums in draining marshes, lakes, and ponds, and in controlling the course of rivers and torrents in Northern and Central Italy. Valuable documents, not for sale, however, treating of these works have been published by the minister of public works. As yet no government report has been published treating of works of irrigation, and to get at figures it would be necessary to apply to the several prefectures of the several provinces.

By the law of December 25, 1883, the Government is empowered to loan funds (principal payable in thirty years) at 30 per cent. to irrigation associations (consozzi) and to provinces and communes for the purpose of carrying on works of irrigation, provided the supply of water to be obtained shall be not less than 25 gallons per second and provided the province or commune advances an amount at least equal to one-tenth of the sum loaned by the state.

REPORT FROM CONSUL JONES ON IRRIGATION OF ORANGE AND LEMON GROVES IN SICILY.

In Sicily, generally speaking, no attempt is made to grow oranges or lemons unless it be possible to water the trees during the summer months. There are, however, favored spots (for instance near Aci Reale, 40 miles south of Messina) where, owing to water veins in the subsoil, the trees retain their vigor during the summer. The proportion of non-irrigated to irrigated groves is as 1 to 15 (in extent).

One hundred ten-year old lemon-trees that are watered produce on an average 15,000 lemons, whereas one hundred trees that receive no water (other conditions being equal) produce but 10,000 or one-third less.

The groves are watered from twelve to twenty-five times during the summer, *i. e.*, either once every two weeks or once a week, and at each watering at least 350 cubic meters should be allowed to the hectare (1 hectare=2.47 acres).

At the last spring working of the trees the land is trenched in order to obtain an equal distribution of the water.

Parallel trenches are opened (generally about 6 inches deep and 8 inches wide at the bottom) between the rows of trees, the intermediate space being divided into symmetrical squares or divisions.

If the grove be very level the water is carried from the distributing reservoir by lines of brick pipes (brinze) open on top, resting on narrow stone walls built with the necessary incline to reach the most distant point from the reservoir.

The system is applied to the irrigation of groves where the water supply is abundant and is derived from a stream or spring. Oftentimes when the water must be pumped up by horse-power the tenant, unless it be otherwise stipulated in the contract, will so arrange his trenches as to collect the water in a basin at the foot of the trees. This method is not to be commended, for it retards the developement of the fruit, of the lemons more especially, and predisposes to gum or foot-rot.

One-year-old orange and lemon trees should be watered once a week; three-year-old require water once every twelve days; from the fourth to eighth year, once every two weeks. With the bergamot, however, weekly irrigation is required during the life of the tree. It is always preferable to irrigate during night-time. Isolated trees are sometimes watered by sinking an earthen pipe (3 feet long by 4 inches in diameter) not far from the trees, and filling the same with water. This method has the advantage of causing the tree to send its roots down. The beds of the torrents suck down the water from the springs on the hill-sides. To bring this water to the surface, oblique ditches are cut across the torrent-beds down to the water veins, and a drain (provided with numerous loopholes) in masonry is put in to collect the water. These drains, following more or less the trend of the land, carry the water into the groves to the right and left.

Bastard fruit, *i. e.*, fruit maturing out of season, always commands good prices; hence it frequently happens that tenants allow the trees to go without water during June and July (the trees sicken badly; the leaves turn yellow, and there is great loss of vitality), and begin watering heavily and frequently in August, to form the trees to put on blooms in September, and in that way produce late fruit.

REPORT FROM PHILLIP CARROLL, U. S. CONSUL, PALERMO, SICILY.

(1) There are 508,601 hectares of land embraced in the Province of Palermo, of which one-fortieth is cultivable and irrigable. Nearly 176,000 hectares are under irrigation, yielding on the average an eighth per cent. crop.

(2) Water is derived principally from deep wells, pumps, and reservoirs, the latter being supplied by means of earthen and iron tubes or pipes communicating with the adjacent mountains, as well as by rivers, streams, springs, and falls in a very limited degree, during certain months of the year. The supply of spring water is, however, said to be decreasing.

(3) A pamphlet upon the system of irrigation in the Province of Palermo, by Prof. Ferdinando Alfonso, kindly furnished by the prefect of this province, is inclosed herewith, as to the character of the works used in irrigation.

(4) The distribution of water is governed by its owners, viz, the municipality, the Government, and private individuals, and is based

upon the measures adopted by the municipality of Palermo centuries ago.

The amount of water used on the average is from 300 to 350 cubic meters per hectare of land.

By the system in vogue nearly 17 liters of water can be conveyed to a designated point per second, and an area containing nearly 13 acres can be irrigated weekly, the charge therefor being 5 lire per hour.

Irrigation is commenced on April 15 annually. For obvious reasons it is not resorted to during winter, excepting in prairie lands for promoting the development of grass.

(5) The average annual temperature of the Province of Palermo is 17° centigrade.

In the mountainous regions the climate is temperate, and on the seacoast very warm.

A characteristic of the province is the almost absolute absence of rain from May to September.

The average annual rain-fall of the province is 59 centimeters. Rain later than May is rare and generally meager, and should the usual copious spring rains fail to make their appearance crops suffer severely.

(6) As stated, the present system, consisting of pumps, wells, falls, reservoirs, etc., has obtained for centuries, under the auspices of the municipality of Palermo monasteries and private persons, but since 1866 the Government has controlled the water belonging to religious bodies, it having in that year confiscated all property belonging thereto. The Government either sells or rents this water. The expense is defrayed by the respective owners.

Cloudbursts or spouts 81, 144, 160, 161, 218
Companies as carriers 65
Conservation of storm or surplus 95
Current meters for measurement 158
Dakota sandstones, derived from 50-52
Disappears in sand 36
Distribution of 140
Division of the, through the States 27, 38, 39, 63, 64, 65
Division of, by drainage districts 64
Donner Lake, from 103
Duty of 19, 20, 134, 152, 157, 171
Equivalents of units used in measuring 229
Flood 20, 22, 24, 25, 28, 31, 40, 77, 81, 138, 144, 160, 172, 206, 216, 217, 218
extreme 30
Pacific coast, on 214
time 26, 41, 72, 137
Flow of 18, 36, 123
mountains of New Mexico, from 20
Rio Grande, in the 105
of, at a particular point, how ascertained 214
Gauging, of 72, 172, 173, 199
stations, for 74, 147
river, height, of 158
Gila, in the 33, 35
Head, American River, of 181
Carson, of 149
Colorado, of 17, 161
Missouri, of 43
of, in mountains 15
Rio Grande, of 27
International problem, at El Paso 32, 43, 63, 105
Interstate problem, of 63, 65
Irrigation by storage of storm 46
lateral streams 33
Jemez River, of, discharges into sand 30
Lost in sand, Saguache River, of 23, 28
Arkansas, of 20
Maximum duty of 20
fall of, basins 138
Measurement of 171, 172, 202, 203
Minimum fall of, basins 138
Mountain of, flowing into Rio Grande 27
National Yellowstone Park, of 243-245
Nile, Egypt, of 43
Overflow dams, of 218
Percolation of, through sand 36
great valleys 98
Point of Rocks, non-irrigating season 27
Puerco, of the 30, 31
Pumping, an American invention 34, 35
Quantity of sediment in 74
Return, conditions affecting 19
Republican Basin surface 97
Rights of 24, 29, 30, 66, 196, 201
Sacramento, of the 40, 41
Sand reservoir, in 169
Seepage of 18, 97, 98, 171, 228
or from Missouri 96
table of measurement of 230, 231
Sheds 80, 137, 209, 238, 239
in certain cañon 123
Silt 21, 22
carried by the Rio Grande 76
Sink at Tucson 36
Sources of supply 45, 46, 47, 53, 54, 55, 232

INDEX TO REPORTS OF UNITED STATES CONSULS.

Page.

- Africa, South, irrigation in 308, 309, 310, 311, 312
  - basins for storage 311
  - Cape Town 308
  - Irrigation in:
    - Act for promotion of 309
    - By private owners 309, 310, 311
    - Cape Colony, in 309
    - Land under 311
    - Orange Free State, in 309
    - Van Wycks Valley, storage in 311
  - Rain-fall in:
    - Lack of 311
    - Table of, for districts, 1888 311
    - Rainy seasons 308, 310
  - Rivers of 310
  - Surveys:
    - Geological, of 310
    - Topographic, of 310, 311, 312
  - Table-land in 311
  - Water:
    - Boring for 312
    - Evaporation of 312
- America, Central, Irrigation of:
  - Guatemala, in 255
  - Nicaragua, in 255
- America, North:
  - Mexico:
    - Cariel, Luis C., deputy president senate 254
    - Cities in:
      - Cantla 252
      - Guaymas 251
      - Mexico City 251
      - Saltillo 250
    - Climate in, character of, in irrigated regions 253
    - Crops, quantity and quality in 252
    - Cubas, A. Garcias, historian 253
    - Dams of masonry in 252
    - Department of public works in 254
    - Diaz, Porfirio, president of 252
    - Fruit trees in 252
    - Irrigation in 250, 251, 252, 253, 254
      - Antiquity of system of 251
      - Coahuila, in 250, 251
    - Landa y Escandon, Guillermode, secretary 254
    - Pacheco, Carlos, secretary of state 254
    - Plantations in 252
    - Rain-fall in, annual 253
      - scant 251
    - Riba y. Echeverria, A., deputy president 254
    - Sanches, Castellanos, senator president 254
    - Seasons, rainy, in 251, 252
    - Soils of:
      - Alluvial valley 253
      - Black loam of 253
      - Rich land 250
      - Sandy 251
        - table lands, on 253

IRRIGATION

IN

THE UNITED STATES.

BY

RICHARD J. HINTON.
[*Special Agent in charge of Artesian Wells Investigation*, 1890,
Department of Agriculture.]

BEING A SECOND EDITION OF MISCELLANEOUS DOCUMENT NO. 15,
FORTY-NINTH CONGRESS.

WASHINGTON:
GOVERNMENT PRINTING OFFICE.
1890.

IRRIGATION IN THE UNITED STATES.

EXTENT AND METHODS. AREA OF RECLAMATION. THE STATISTICS THEREOF. ARTESIAN WELLS. LAWS OF STATES AND TERRITORIES. WATER SUPPLY. RATES AND DISTRIBUTION; WITH BRIEF SKETCH OF FOREIGN SYSTEMS, ETC., ETC.

PREPARED BY

RICHARD J. HINTON.

BEING A

SECOND EDITION OF SENATE MISCELLANEOUS DOCUMENT No. 15, 49th CONGRESS.

IRRIGATION IN THE UNITED STATES.

[Prepared by order of the United States Senate Special Committee on Irrigation and Reclamation of Arid Lands.]

PART I.

THE ARID REGION.

An inquiry into the progress and present condition of irrigation in this country necessarily involves a consideration of the extent and character of the area within which the annual rain-fall is not sufficient for the industrial uses of the people. Such an inquiry, broadly defined, involves the extent of the fall of rains or snow within the area indicated; also the evidence obtained as to increase or decrease of precipitation resulting from agricultural settlement or of pastoral occupation, the increase of humidity of earth or air, the destruction of the timber mainly by its use for settlement purposes, the effect of the destruction of the native grasses and the substitution of cultivated varieties; also the sources of water supply, their character, uses, conservation, the means, natural and artificial, employed for their distribution, and what has been and is being accomplished in the way of artificial methods of water distribution and economy, and the laws and customs pertaining thereto. More than any of these, however, it relates itself fundamentally to the largest questions of physical geography. The topographical configuration involves, indeed it controls, the whole matter of aridity, because it determines all climatic considerations. The probability of reclamation by means of irrigation is primarily by the configuration of a given hydrographic area.

Incidentally, the questions arising from deforesting, on the one hand, and of arboriculture, on the other, are related to the inquiry, and have been brought out to some extent. The aim has been to give the actual facts upon these subjects, so far as they could be supplied from observation, experience, experiments, and realized results. This effort has been measurably successful. It has brought together a mass of facts and observations that shed much light on the questions involved, giving a broader idea of the importance of irrigation, and adding greater value to a very large area of the United States, of whose agricultural capabilities but small account has heretofore been taken. It will be developed by the facts herein presented that the area of the irreclaimable arid lands within the boundaries of the Union is, comparatively speaking, quite moderate in its extent. There is, however, a very large area, embracing at least one third of our total land service, wherein the water supply, whether subterranean and surface-flow or in the form of precipitation, is both inadequate and irregular in character.

The eastern boundary of this great area may at present be assumed to be the one hundredth meridian of west longitude. The western boundary may be in part placed at the Pacific Ocean, though more accurately the Coast Range of California would be the line. The northern boundary is the British territorial line west from the one hundredth degree to the summit of the Sierras, or the one hundred and twentieth meridian. Following the summits of the main range, the northwest line would deflect to the central portion of Oregon, following the southwesterly bend of the mountains down to the northern boundary of California. The southern limit of this dry area would be the northern line of Mexico, and thence south by east, along the Valley of the Rio Grande, down to the Gulf of Mexico. The area then, east and west, through its central and larger portion, runs from the one hundredth meridian to the one hundred and twenty-fourth degree of west longitude, and in its greatest prolongation north and south from the forty-third to the twenty-seventh degree of latitude. In its more northern portion it runs east and west from the ninety-eighth to the one hundred and twentieth degree of west longitude. The larger portion from north to south is embraced between the thirty-second and forty-third degrees of latitude, with the sub-arid or semi-humid area, the eastern line of which, though irregular, may safely be stated as the ninety-seventh meridian, the total area extends east and west for nearly twenty-eight degrees of longitude.

These lines cover nearly one-half of the States of Kansas and Nebraska, both States of Dakota, the whole of the States of Colorado, Montana, and Nevada, with nine-tenths of California, one-third of Texas, and about one-third of Oregon; also the Territories of Wyoming, New Mexico, Utah, Idaho, and Arizona, with at least one-third (east of the mountains) of Washington. This embraces about one-third of our whole territorial surface, inclusive of Alaska. How much of the latter-named Territory may be wholly or partially arid or desert in character can not yet be estimated. The east and west lines of this dry region, then, are, in the widest section, over 1,300 miles apart, and in its greatest length, the northern and southern limits are about 1,000 miles apart. If the whole region were compactly arranged it would make a block about 1,000 miles square. The area thus indicated may be subdivided again into three broad divisions, as follows:

(1) The plains region, running north and south from the British American line to the lower portion of the Rio Grande Valley in Texas, and east and west from the one hundredth to the one hundred and fifth degrees of west longitude. This division may be broadly declared to have a general rise and altitude of from 1,500 to 5,000 feet, though it will fall below that at either end of the area. It is but sparcely supplied with streams, which are mainly fed from mountain sources; the annual precipitation is nearly everywhere below a reliable amount for economic uses. In the central portion this precipitation will not, under favorable conditions, exceed 18 inches per annum in the eastern part, and as we go westward it diminishes to 12 and 15 inches per annum.

In the southern (Texas) portion of this area the rain-fall will somewhat exceed 20 inches on the east, decreasing until, on the northwest, it will reach only 8 to 10 inches in the most favorable seasons. In the northern or Dakota portion the average is more evenly maintained. This division will include the western half of Kansas and Nebraska, one-third (or the eastern foot-hills and plains region) of Colorado, the major portion of Dakota, the eastern half of Wyoming Territory, and one third or more of the Indian Territory and Texas, with about one-fourth (or the eastern part) of New Mexico. It is drained by a number of streams, some of them of importance, and is bounded on the east and north by the Missouri River and its afluents, and by the Pecos and

Cimarron Rivers on the west and southwest. Its soil is almost uniformly fertile. Natural grasses of most nutritious quality are found throughout its area. It is the most important grazing section of the West.

Large farming settlements are moving steadily and compactly westward from the eastern line. At various points in its western portion there are important farming communities, created mainly by the use of water as applied through irrigation ditches and by other means of storage and distribution. The valley of the Upper Rio Grande, from the San Juan Range in southern Colorado, to where the river debouches from New Mexico into Texas and becomes the boundary-line between the United States and Mexico, has for many generations been the seat of local and unsystematized irrigation works. The Pueblo or town-dwelling Indians have for centuries practiced it. Since the Spanish conquest, in the sixteenth century, the mixed Mexican people who have inhabited this district have always been obliged to irrigate in order to cultivate. In these latter days our own more enterprising people are inaugurating and carrying on larger enterprises and projects, whose advantages are already perceivable.

(2) The second great division can be more distinctly characterized as the arid section of the United States. It lies between the one hundred and fifth and the one hundred and twentieth meridians, taking in the whole of our intra-mountain region, from the foot-hills of the Rockies to the lower slopes and foot hills of the Sierras Nevada in California, and extending north and south from British America to Mexico. Within this area, except on the higher and arid heights of the ranges, principal or secondary, there is generally good pasturage for cattle. The natural grasses are sun-cured, and afford ample food and range for many million head of cattle.

The problem of water supply is, however, one for serious consideration. There are desert tracts and areas within this great region which are undoubtedly arid and desolate to the extent of irreclaimability. Their extent is a matter yet unsettled, especially in view of the great enterprises projected and in progress in both Colorado and California. Even the mountain plateaus, which, from altitude as well as aridity would seem to be undoubtedly sterile, may yet be found useful, not only in providing for cattle, but, possibly under systematic plans of forest-culture, they may be made the means of protecting the water sources and otherwise favorably modifying climatic and terrene conditions.

The defined outlines of this second division embrace the great basin section, of which Utah and its water reservoir—the great Salt Lake—are the dominating physical and geological features; the Colorado plateau region, which occupies the larger portion of Southern Nevada and Northern Arizona; the beautiful parks of the Rocky Mountains or the eastern flank and ranges of the North American Cordillera system; the table-lands of southern Arizona, and the great valleys and basin formed on the north by the Columbia River and its important affluents in eastern Oregon, Idaho, and Montana.

Arid and desert as this stupendous mountain system may seem to be, it will be found on examination to have large sections capable of agricultural uses, and also to hold within its borders such sources and supplies of water as, properly conserved, protected, and distributed, under the wise and conservative direction of the national and State Governments, will be found of ample utility for the purposes (1) of larger pastoral uses; (2) of more limited and localized, but still extensive, agricultural purposes; and (3) as storage and reservoir sources, from which at no distant day the life-giving waters may be conveyed to and distributed over vast areas, which even our present limited experiences prove to be convertible into fertile farms.

A glance at a good topographical map will indicate to the observant eye the areas under reference. For example, the central section of the Rockies (in Colorado, Wyoming, and a portion of New Mexico) contain the sources of important rivers. This hydrological area is extensive, as there are numerous lakes, some of considerable size, while the snow precipitation is also quite heavy.

Inquiry and examination will satisfy the inquirer that in the extreme west the higher Sierras yield from the snow precipitation alone an amount of water which, under proper engineering conservation and wise plans of distribution, carried out for the common weal rather than for corporate profit, would supply the whole great valley and foot-hills region of central and southern California, now being so largely developed as a wheat and fruit growing region. The eastern slopes of the Sierras belong as drainage area to the huge hydrographic basin of which Nevada is the chief portion. The snows and storage of that region should readily reclaim 3,000,000 acres in western Nevada.

In the northern portion of our intra-mountain area the hydrological system, comprising the Columbia and Snake Rivers and their affluents, will certainly give a sufficient water supply both for pasturage and agriculture.

East of the Cascade Mountains the climate and natural features of the country are very different from those of the great basin lying west of them, so that the popular divisions, eastern and western Oregon and Washington, are fully warranted. In the eastern section the thermometer is much higher in summer and lower in winter than in the western section. The rain-fall is not half as heavy. From June to September there is no rain. The winters are short, but occasionally severe. Snow seldom falls before Christmas, and, though it sometimes lies from four to six weeks, it usually disappears in a few days. The so-called "Chinook," a warm wind, blows periodically, and melts deep snows in the course of a few hours.

In Eastern Oregon and Washington spring begins in February, and lasts until the middle of May. At this season rain falls in sufficient quantity to give life to vegetation and insure good crops. The average temperature is 52°. The rain-fall of the year does not average more than 20 inches. South of the Snake River it is not more than 15 inches, increasing gradually to the northward.

In the southern portion of this area, where the Colorado plateau descends to the valleys of the Gila, Colorado, and Rio Grande, forming the table-lands of Southern Arizona and New Mexico, there has already been utilized a water supply sufficient for cattle, and in several extended portions, as in the valleys of the Gila, Rio Verde, Salt, Colorado, Chiquita, San Pedro, and Santa Cruz Rivers, almost enough to meet the present agricultural and horticultural demands has been turned to account.

It may be estimated, then, that, of our whole intra-mountain region below the timber line as herein outlined, at least 60 per cent. affords fair pasturage, with sufficient watering-places, though often at long intervals apart, and subject to various limitations, which are rapidly being in a degree overcome, and will hereafter largely disappear as more attention and skill are directed to the subject. The facts gathered from Utah and Nevada will show how large are the possibilities of improvement in this direction. No really accurate estimate can be made as to the proportion of this intra-mountain area that may be reclaimed for arable and horticultural purposes; but it is not extravagant to claim that when the accessible water sources shall be brought into use, one-fifth of its acreage (as already defined) may be so utilized. In a very large portion the per cent. will be quite small; in other portions it will greatly exceed the general estimate here made. It must be borne in mind that in both estimates the higher mountain sections, embracing at least one-fifth of the whole region, are excluded. Yet, on the summit of the highest plateau region in northern Arizona, for instance, cattle are successfully wintered at an altitude of from 7,000 to 10,000 feet above the sea.

(3) The third division, which might fairly be ranked first in point of interest, embraces the Pacific coast region from the western slopes of the Sierra Nevada (in California) to the ocean, and takes in the great transverse valley troughs or plains cradled between the Sierra foot-hills and the Coast Range, the great wheat granary of the Golden State, and also the fruit-growing section, yearly rising in importance.

In treating of these three divisions of the arid region more in detail they will be taken up in inverse order, beginning with the one named last in the above statement.

THE PACIFIC COAST DIVISION.

This division embraces the State of California, lying between the one hundred and twentieth degree of west longitude and the Pacific Ocean, east and west, and between the fortieth and thirty-first degrees of north latitude.

In the San Joaquin Valley, at Fresno, and at different points in southern California, as Los Angeles, San Gabriel, Riverside, Anaheim, San Diego, water is found to be attainable at moderate depths, and apparently in all directions. This subterranean supply, wherever it has been reached and utilized, is greatly reducing the need of surface irrigation.

Fruit growers and wheat farmers in southern California unite in the testimony that after irrigation has been practiced for some years a given supply of water suffices for a largely-increased area, the explanation being that when water is first applied to arid land a large part of it sinks deep into the dry earth, or is carried away latterally by seepage; whereas, when the lower strata and, to some extent, the lands adjoining those under irrigation, are moistened, the amount of water absorbed in excess of the actual needs of vegetation becomes comparatively small. How much effect this increased humidity of the soil may have on the atmospheric humidity is not yet known, but the increase of evaporation due to this circumstance and to the cultivation of trees and plants must ultimately produce a beneficial change in this regard.

The full industrial use of water in California must necessarily be governed by the larger topographical and other physical conditions. The precipitation seldom exceeds 22 inches annually, and over a greater portion of the State falls below that figure. The wide range of variation in rain-fall is illustrated by the following facts: At Fort Redding the range of three years was from 15.9 inches to 37.4 inches; at Sacramento the range of seventeen years was from 11.2 inches to 27.5 inches; at Millerton, six years, from 9.7 inches to 49.3 inches; at Stockton, three years, from 11.6 inches to 20.3 inches; at Fort Tejon, five years, 9.8 inches to 34.2 inches; at Monterey, five years, from 8.2 inches to 21.6

inches; at San Diego, twelve years, 6.9 inches to 13.4 inches; at Benicia, twelve years, 11.8 inches to 20 inches. The above figures show the rainfall for calendar years; the following show the amount of precipitation during the rainy season: Clear Lake, 1,300 feet elevation, six years, 16.2 inches to 66.7 inches; Visalia, three years, 6.7 inches to 10.3 inches; San Francisco, twenty-two years, 7 inches to 49.3 inches; Pillarcitos, nine years, 39 inches to 82 inches; Sacramento, twenty-four years, 4.7 inches to 36.4 inches; San Diego, twenty-two years, 4.5 inches to 14.8 inches.

The importance of California warrants a fuller description of the State, its topography, and other conditions bearing on the question of irrigation within its limits. There are two great mountain ranges running northwest and southeast, namely, the Sierra Nevada and the Coast Range. The former is from 4,000 to 8,000 feet high and the latter from 1,000 to 6,000 feet. The two ranges are connected in the southern part of the State at Tehachipi, and in the northern at Mount Shasta. The Sierra Nevada Range extends along the eastern border of the State and is about 450 miles long. The Coast Range extends along the coast to the northern and southern boundaries of the State. The base of the Sierra Nevada Range north of Fresno has an average width of about 80 miles. The Coast Range averages about 65 miles in width. Between the two ranges are the great Sacramento and San Joaquin Valleys, which together are about 450 miles long by 55 miles wide, and may be termed the heart of the State.

In the northern part of the State, and north of the junction of the two great mountain ranges, is the Klamath Basin, through which the Klamath River runs for a distance of 225 miles, between steep hills and mountains and rocky cañons, in a southwesterly course to the ocean. The whole basin of the Klamath is very rugged for a distance of 40 miles from the coast, and along the main river there is very little valley or bottom-land. However, there are several small rich valleys and near the lakes there are large fertile tracts. Pine, cedar, and fir forests cover the mountains, and there are other valuable trees, both on the mountains and in the valleys. In the extreme southeastern portion of the State is the Colorado Desert, about 140 miles long by 70 miles wide, which is the dry bed of a former inland sea. Another great basin, called the Mojave Basin, lying north of the Colorado Desert, extends into the southern part of the State, the surface of which is cut up by many irregular ridges of mountains.

The Coast Range is composed of a multitude of ridges and is intersected by numerous long and narrow valleys of fertile soil, comprising those of the Los Angeles, Salinas, Santa Clara, Sonoma, Napa, and Russian Rivers. The State has numerous small rivers. In the central portion are the Sacramento and San Joaquin, each in its meanderings about 350 miles long. These are the only navigable streams in the State. From the Sierra Range westward into the Sacramento flow the Pitt, Feather, Yuba, American, Consumnes, and Mokelumne Rivers. Into the San Joaquin flow the Calaveras, Stanislaus, Tuolumne, Merced, Chonechilla, and Fresno. Into Tulare Lake flow the Kings, Kameah, Tule, and White Rivers, and into Kern Lake the Kern River. All of these are considerable streams, with an average length of about 120 miles. The upper half of each is in the steep and rugged mountains, where they are torrential in character. After reaching the plain their currents are gentle, and the banks low, fringed with oak, sycamore, cottonwood, and willow.

The rivers of the Coast Range flowing westward into the ocean south of San Francisco are the San Lorenzo, Pajaro, Salinas, Carmel, El Sur, and Cuyama, Santa Inez, Santa Maria, San Buenaventura, Santa Clara, Los Angeles, San Gabriel, Santa Ana, Santa Margarita, San Luis Rey, and San Diego. Many of these are constant streams to within 10 or 15 miles of their mouths, and all of them pass through rich valleys. North of San Francisco the streams of the Coast Range which empty into the ocean are the Russian, Eel, Elk, Mad, Klamath, and Smith Rivers, besides many others of less importance, all of which are permanent streams, bordered with narrow valleys at the foot of the mountains. To all of the rivers of the State flow many small tributaries. There are several important lakes, the Tulare, Owens, Kern, Clear, Klamath, Goose, Fall, Eagle, Honey, Elizabeth, Tahoe, Mono, and Dry Lakes. There are also a number of smaller ones.

The southern portion of the great interior basin of California is commonly known as the San Joaquin Valley, although it comprises the San Joaquin, Tulare, and Kern Valleys. The Tulare Valley is separated from the first named by a low ridge of land, scarcely noticeable, and in times of high water the southern lakes and rivers find an outlet through Fish and Fresno Sloughs into the San Joaquin River, thence to San Francisco Bay. Properly, there is no division lying between the San Joaquin and Sacramento Valleys. The greatest length of San Joaquin Valley is 260 miles, the width varying from 30 to 70 miles. The area is 11,290 square miles, or 7,225,600 acres. The eastern and western sides of the valley slope from the base of either range of mountains towards the lakes or streams in the lowest part, at the rate of 5 to 8 feet per mile; also northward to tide-water in San Francisco Bay, with a general fall of 1 foot to the mile.

The Mount Diable or main Coast Range on the west side of the valley has an average height of about 1,700 feet. The Sierra Nevada Mountains on the eastern side of the valley rise to a much greater height. Mount Whitney, in Tulare County, has an altitude of 15,056 feet, and is the highest peak within the United States. From this mountain the summit-line of the range gradually lessens in height towards the north and more rapidly to the south. These mountains are rugged and broken, sharp, rocky ridges and granite spires rising abruptly to great altitudes. In the small valleys between these ridges is perpetual snow, and about the base of Mount Whitney are a number of small glaciers. This region has some of the wildest, grandest, and most beautiful scenery in the world. The San Emidio, or Tejon Mountains, a spur running at right angles to the Sierra and Coast Ranges, and joining the two, form the southern boundary of the San Joaquin Valley. The foot-hills commence in the northern part of Fresno County at an altitdue of 300 feet above sea level, and in the extreme southern end of the valley at a height of 400 feet. In the hills are many valleys, some of them large and level, others more uneven.

In the Coast Range there are few valleys. About the base of the range are gently-sloping table-lands at an altitude of 100 to 250 feet above the valley, from which the mountains ascend to sharp and narrow ridges cut transversely at intervals of a few miles by natural passes extending through the range. The flanks of the Sierra broaden towards the south. The Sierra foot-hills in the portion of Tulare County, midway between the northern and southern boundaries, rise suddenly from the plain, but to the northward and southward, in Fresno and Kern Counties, the slope is more gradual, the hills lower, and the belt wider.

THE RAISIN VINEYARD REGION.

To the eye of the traveler the plain generally presents a very level surface. In Fresno County, on the eastern slope of the valley, are scattered hillocks 20 to 30 feet in height, with a wide base, rendering them inconspicuous even at a short distance. These are not observable elsewhere in the Southern San Joaquin Valley. Extending along the entire length of the eastern side of the valley, near the foot-hills, is a belt of uneven country known as "hog-wallow" land. These "hog wallows" are little mounds ranging from a few inches to 3 or 4 feet in height, averaging 1 to 2 feet, with a diameter of 16 to 50 feet. There are no deep river-beds traversing the upper part of the valley, although further north these are common. The beds of the southern streams, in fact, are in almost every case higher than the general level of the plain, having been built up into low, wide ridges, by the alluvium deposited during the rainy season through a long series of years.

Fresno, Tulare, and Kern Counties form the southern part of the San Joaquin Valley. The three counties have an aggregate area of 21,770 square miles, or about 13,932,800 acres. Of this large extent of country 13,885 square miles, or 8,886,400 acres, are mountain and hill land; and 7,885 square miles, or 5,046,400 acres, are in the valley, making a body of arable land in these three counties (deducting the surface covered with water) equal to some of the larger Eastern States. The land is divided among the counties as follows: Fresno, 4,480 square miles, or 2,867,200 acres, of mountain and hill land, and 3,520 square miles, or 2,252,800 acres, of valley land; Tulare, 3,835 square miles, or 2,454.400 acres, of mountain and hill land, and 1,775 square miles, or 1,136,000 acres, of valley land; Kern, 5,570 square miles, or 3,564,800 acres, of mountain and hill land, and 2,590 square miles, or 1,657,600 acres, of valley land, including the gently sloping plain skirting the base of the hills. There is a more gradual ascent from the valley proper in Kern than in either of the other two counties. The numerous valleys, large and small, in the mountains and foot-hills are not estimated as valley land.

THE SAN JOAQUIN ARTESIAN WELLS.

There is a large portion of the southern San Joaquin Valley that is not wholly dependent upon the streams for irrigation, considerable water being obtainable from artesian wells. The artesian belt extends from one end of the valley to the other. A good flow is usually obtained in boring to a depth of 300 to 600 feet. The first successful boring for artesian well water in Tulare County was made by the Southern Pacific Railroad in 1879 near Tipton, and a flow rising half an inch above the rim of the casing was secured at a depth of 310 feet. The well is on the eastern margin of the belt. This water was used for irrigating a 40-acre tract of forest trees, which it did successfully.

No rock is encountered in boring, strata of sand, clay, and gravel succeeding one another. It is therefore necessary to use iron casing the whole distance, which is forced down after the auger. The depth at which the first water-bearing stratum of sand or gravel is penetrated is from 310 to 640 feet, although some of the wells have been put down to a depth of 800 feet, passing through several of these strata. The deepest in Tulare County are in the northwestern part, near Lemoore. The section in which the greatest number of good, flowing wells have been obtained is west of the Tulare and near Tipton, the water from some of them rising to a height of 5 or 6 inches above the casing. Wells are also shallower here than about Lemoore. The average depth in Tulare County is about 450 feet. There are in Tulare County about three hundred wells. It is impossible to give the exact number, as so many new ones are being bored. In Kern and San Bernardino Counties the number is not less than five hundred.

In Fresno County fewer wells have been bored. In the southern part of the county water is obtained in one well at a depth of 152 feet. Others have been bored in the region bordering on the San Joaquin River, the depth of these averaging from 150 to 200 feet. In Kern County, at the southern extremity of this great basin, artesian wells were bored several years ago and water was obtained at a depth of 200 to 250 feet, the average depth being less than in Tulare County. Some fifteen or twenty wells have been bored in the county. One, 470 feet deep, furnished about 30 gallons per minute. Others have been bored north of Poso Creek, in the region about Delano and Alila, and elsewhere in the county. The average flow from the wells of Tulare County may be placed at 2½ inches above the casing.

The quantity of water furnished by a well of this capacity is about 247 gallons per minute, or a little more than half of a second-foot. In parts of the San Joaquin Valley shallow wells have been known to fail after two or three successive years of light rain-fall and to flow again after a wet season. This has not happened in the southern portion of the valley. The deeper wells continue to flow regularly. It is claimed that some of the wells in Tulare County will each irrigate 160 acres of land thoroughly, and after the ground has been irrigated and cultivated a number of years and the methods of applying the water perfected a greater acreage can be successfully watered. More recent observations show that these wells are periodical as to flow, being larger and with more power when the mountain snows are melting than at any other time.

The Mussel Slough region in Tulare County was the first to be irrigated on a large scale, and soon became famous for the productiveness of its land. In the foot-hills there is generally sufficient rain, except in very dry years, to mature crops. Where the soil is loose and sandy and where irrigation has been in use for a term of years little water is required other than that supplied by the rain-fall, the ground being sufficiently moist from seepage. In places moisture will permeate the ground for miles from the ditches. In some portions of Kern County the farms comprise from 640 to 1,800 acres, and the checks made for irrigating are surrounded by strong, low embankments, made with a view to permanency. The ditches are made on the highest land, and the levees inclosing these irregularly-shaped checks are built so as to take advantage of the natural inequalities in the surface.

VALUE OF THE FOOT-HILLS.

The foot-hill region contiguous to the great valley which has been frequently referred to deserves more extended notice. This belt is of varying width, extending along the Sierra Nevada Mountains. In the mild climate of the Southern Joaquin plain it is most valuable for the growth of citrus and other semi-tropical fruits. It is particularly adapted to early fruits of all kinds. It has already been stated that fruit ripens much sooner in the orchards of the Fresno and Tulare County foot-hills than on the plains. The same is true of Kern County. Experience demonstrates that in the valley at the mouth of Kern River Cañon, twelve miles from the Southern Pacific Railroad at Sumner, frosts begin one month earlier than in the valley, and cease a month earlier in the spring, and during the coldest period are less severe than on the plain.

Peaches in the foot-hills have ripened a month earlier than on Kern Island; all kinds of stone fruits mature early, while other kinds that do not bear well or regularly in the valley grow to perfection here. An isothermal line drawn through the axis of this belt would traverse the lower and more easily cultivated portion of the foot-hills, and at the southern end of the valley would extend upward and inland to the abrupt mountain wall where Kern River Cañon bisects the range, where it would approach nearer to the valley than farther north, owing to the topography of the mountains and not to other conditions influencing climate. Above the thermal belt, extending through the region of black oak to and into the pine and redwood forests, is an extensive area adapted to the production of a great variety of crops, and particularly to those fruits that require a cooler climate than that of the lower foot-hills and plain. The soil is rich, but the greater part of the hill land is covered with a dense growth of chamiso, manzanita, chaparral, and other brush, which must be cleared before the land can be cultivated.

Small clearings have already been made, and the result has been to encourage others to enter or purchase and do likewise. At no distant day this will be an important section of the agricultural and fruit-growing portion of the three counties named. It is a healthy region. The rain-fall is greater than in the valley, and by conducting water from the mountain streams by the system of piping employed in other parts of the State a sufficient supply can be obtained to irrigate all the best cultivable land, and by the conservation of water in reservoirs during the wet season the small streams could be depended upon to furnish a sufficient supply for a large aggregate area not readily reached by the main streams. Above an altitude of 1,200 feet in Fresno, 1,500 feet in Tulare, and 2,000 in Kern County there is sufficient rain-fall to make irrigation useful but not an absolute necessity.

In the region midway between the plain and the mountains proper the hills are generally precipitous, and although small valleys are numerous, there are few of any considerable area. Land in the southern San Joaquin Valley remote from water supplies has in only a very few instances advanced materially above Government price; whereas that lying contiguous to or supplied with water has advanced several hundred per cent. in value, having been converted from grazing to productive agricultural and fruit land. In Fresno County only has the colony plan of settlement been carried to any great extent. At present there are two colonies in Tulare County, and one or two large tracts of land for sale in lots of 10 to 40 acres. Twenty acres are sufficient for fruit growing, and 40 acres is the largest tract that one man or family should attempt to cultivate, for it pays better to give careful attention to 20 or 40 acres than to imperfectly work more. The first colony started in Fresno County was the Central, near the town of Fresno, on the west side of the railroad. The land on which it was located was a treeless, uninviting plain, and, except in the wet season, verdureless. Now the elm, fig, cherry, and other trees give names to the avenues along which they are planted, and the tract presents a succession of flourishing orchards and vineyards, with scores of beautiful and comfortable homes, surrounded by shrubbery, green lawns, and flowers. Other colonies have since been started, and are in a more or less advanced state. The principal ones are the Washington, Nevada, Fresno, Scandinavian, Easterby, and American, which follow in the order named.

THE DRAINAGE BASINS.

The area of California in its relations to irrigation falls into the following divisions:

(*a*) The natural area of sources, supply, and reservoirs; that is, the higher portions of the Sierra Nevada, upon the western flanks and summits of which the snow precipitation is heavy, whose physical formation creates the great catchment basins, and whose altitude is sufficient to break, deflect, and desiccate the great moisture-bearing currents from the Pacific Ocean.

(*b*) The foot-hills region, extending from Mount Shasta to the San Bernardino Range. This is the seat also of the important mining operations of the State. It is, consequently, the area in which the water-supply section has been largely drawn upon and made extensively available by means of catchment areas, dams, ditches, and flumes. It is also especially in what is designated as the lower foot-hills where the altitude is below 2,500 feet, an area in which these supplies and distributing agencies, natural and artificial, have been extensively utilized for agricultural and horticultural purposes.

Experience has proved that in this subdivision of the State, which for all practical purposes embraces nearly all of Northern California, irrigation must, for such industrial purposes, be heavier and more continuous than elsewhere. Irrigation enterprises therein have up to date been largely of a personal and individual character, except where the hydraulic mining companies have utilized their larger water-works and channels, with the surplus waters they controlled, by selling the latter to the farmers and horticulturists of the region.

(*c*) This subdivision embraces the great valley region of the State, its most important wheat and grain growing section, and includes the extensive drainage basins of the Sacramento, San Joaquin, Feather, Bear, Yuba, American, Cosumnes, Mokelumne, Tuolumne, Merced, Kings, Fresno, Kern, and other streams, large and small. It covers an area of over 34,000 square miles, divided into sixteen counties, within which every problem connected with the industrial use of water and its conservation, legal and practical, is in process of both application and discussion. The most extensive canal system, and the combination of farming interests in the control of supply, or the application of capitalistic enterprise to induce land settlement primarily and water purchase subsequently, are to be found therein.

There are also, as already noted, well-developed artesian belts in the upper portions of this region. The lower portions are subject to tidal overflow and river inundations, while the existence of water at a moderate depth is being demonstrated in almost every portion of the great valley areas. This region embraces not only the major portion of the wheat-producing area, but is also the seat of large viticultural and horticultural activity.

PLANTING AND SUB-SURFACE WATER SUPPLY.

Perhaps the most gratifying as well as significant fact developed by the irrigation experience of California, especially in the valley region, is that connected with quality of the soils, which are generally of great thickness and tenacity. Underlying the surface soils there are found almost everywhere at moderate depths, impervious strata, by which the water drawn too rapidly from the overdrained surface has been happily preserved. Owing to this almost generally established condition of things, water throughout the northern as well as the central portions of the State is being obtained from ordinary wells. It is pumped to the surface and distributed by the agency of the peculiar wind-mills in use, which are now known in all parts of the world.

The altitude of the California valleys is nowhere very great, and the lower portions are at but moderate heights above sea-level. That of the foot-hills region is from 2,500 to 4,000 feet. California experience brings into prominence the question whether the cultivation of the soil in surface-dry and wind-desiccated areas, such as the valleys and lower table-lands of that State were assumed to be but a few years since, does not of itself tend directly to an increase of surface humidity by capillary attraction, or the drawing upon the water supplies that are unquestionably found in the underlying strata. Another question suggested is, whether such supplies are not to be found flowing below or underlying considerable areas of the valley plains and table-land regions of Central and Southern California and elsewhere within our dry areas. The precipitation of rain and snow, with the annual melting [illegible] the latter, would be in itself sufficient to feed such subterranean bodies.

It is evident that these aqueous supplies do not directly flow to the ocean within the hydrological channels and basins that have been worn through the surface and other strata. The streams and rivers of California do not carry volume enough to account for the amount of deposition that must occur within the sub-division designated as the source and supply area of the Sierras. If subterranean bodies of water exist they will be utilized by borings. The high altitude at which waters disappear into the earth must give them, when arrested under the table-lands and plains below by impervious strata, a force ample to propel the same up and above the surface, and to give them the value of living perennial streams or springs. In fine, there are two sources of subterranean waters to be utilized in California for fuller industrial purposes. The first is the water arrested in its flow from the surface at moderate depths, and which can be reached and drawn upward by the loosening of the soil consequent upon cultivation, and by the hardy and penetrative qualities of the plant roots. The other source is to be found in the deeper bodies that are presumably the lost and sunken floods of the Sierras. That such bodies exist there is more than mere conjectural data to indicate.

RECLAIMABILITY OF MESA AND DESERT LANDS.

Passing from these points, the other division of southern California embraces some of the features of both the valley and foot-hills regions. It is also affected in its western portion by the trade winds and other coast influences, and its extreme southern and eastern section is modified and molded by the great Colorado plateau formation of which the boundary mountains and mesas, or table-lands, are in fact a part. There are great stretches of arid mesa, or secondary table-land, which must be counted as desert, though the major portion has native grasses sufficient to feed a large number of animals. There is also sufficient development, especially in Los Angeles and San Bernardino Counties, to indicate the possibility of profitable reclamation in the case of considerable portions of these so-called deserts, provided the waters now available, explored, and in part utilized, can be distributed over their surface.

The southern California division approaches, in many of its products, a semi-tropical fertility and luxuriance. It is the chief seat of the orange culture. The lemon, olive, date, fig, almond, pomegranate, nectarine, and other fruit trees requiring warm and fecund soils, grow in abundance there. The upper or northerly part of this subdivision forms a part of the great wheat-producing area of the State.

The table-land or mesa portions are also extensively utilized for the pasturage of cattle and sheep. In the southern section of California the absence of any considerable hydrological basins with flowing waters in them makes the method of conservation of great significance. The economic use of water therein has almost approached perfection. The conservation of the Los Angeles River and of other similar but smaller streams, within the three great counties into which Southern California is legally divided, is in proof of this.

WATER LAWS AND REGULATIONS.

The practical legal issues involved in the conservation and distribution of water for economic uses within the State of California are of a most serious character.

There are district community methods of control, as seen in the laws and policy found operative within the State. The first comes from the admixture of the Indian community, or pueblo life, with that of the Spanish conqueror, both being affected and shaped by the needs and customs of people to whom irrigation has always been a prime necessity. The Indian, with his tribal, clan, or village organization, has regarded land and water as common or communal property, in the use of which all had a right. The Spaniard regarded the land as his by conquest, but held that the water, being necessary for its full utilization and profit, must be controlled by the king, *i. e.*, the state, and therefore should be for the public use. The English common-law doctrine of riparian rights has no place in the economy of either people. The public charge of the water supply at Los Angeles and elsewhere in southern California illustrates the perfection to which the community may bring control and distribution. The discovery of gold brought with it in California the rapid adoption of a miners' code, both as to the occupation of mineral "claims" and the control of water rights.

This code has become the foundation of nearly all our legislation, State and national, as to the disposition and use of the mineral lands, and, in a minor degree, it has also dominated and shaped the water usages so far as mining is concerned. The public use of water is fairly established in that connection; but as to the other and larger utilization of water in agriculture, the drift of events within the dry area seems to have been for a long time in the opposite direction. This tendency began early in the construction of large works in the upper foot-hills and Sierra regions, for the purpose of obtaining a water supply large enough to carry on the great hydraulic enterprises which, for a quarter of century past, have been so marked a feature of California gold-mining.

The United States Senate Committee on Irrigation sum up the legal relations of water and land as follows:

> The legal questions involved in the beneficial uses of water have been strangely complicated in California. The Indian community system prevailed before and during the Spanish occupation, having been made useful by the missionaries, who obtained such great control of that population. The Spanish conquerors were themselves original dwellers in an arid region When the State passed under the control of this Republic, such small portions of it as were cultivated owed their fertility

entirely to irrigation. The modes of distribution were recognized as being properly controllable by the community. Water was public property. The American miner, with his new enterprises and enormous energy, created a whole code of laws in regard to the use of water. Its basis was the pioneer principle of first come first served, and that has been reproduced in our jurisprudence as "prior appropriation."

In forming a constitution, the people of California incorporated the body of common law. Judges and courts have construed the common law to mean that the doctrine of riparian rights necessary in England and in our Eastern States should be applied to the use and distribution of water to agriculture. It is easy to see that this conflict of prior appropriation and riparian rights must create considerable trouble. A large majority of the earlier irrigation enterprises, generally found in the foot-hills region, were served with water secured under the miners' prior appropriation laws. When the land-owner on a stream demanded his riparian use of the flowing water, litigation or worse at once ensued. At no time, however, were the communities in the southern part of the State organized upon the old Indian and Mexican control involved in this dispute. The prior appropriations had often, it is charged, attempted to monopolize the water supplies, not for their own or immediate use, but for speculative purposes, and as a lien upon the future. This gave some color of equity to the absurd demands for riparian rights, as at times these were sought to be exercised by small land-owners against the large appropriators of water and owners of great tracts of land. A few years since the supreme court of California brought the subject of riparian rights to a crisis by deciding in favor thereof.

As a result of this conflict, California has adopted a plan of co-operative or district control which bids fair to wisely settle all questions of water and its use, of irrigation, construction, and ownership, and of the methods and forces by which these shall be managed and paid for. This is embodied in several legislative acts known as the "Wright Irrigation District Laws." Under these acts the people of any drainage and arable area to be supplied by water from a common source, can, by obeying certain legal requirements, form themselves into an irrigation district, having a common seal, the right to sue and be sued, to make, own, and control irrigation constructions, to issue bonds therefor and pay interest on them, to levy taxes, to meet indebtedness and maintain works, to regulate the use of waters and decide the cost thereof to the farmer and consumer, to condemn lands and water rights, and in short to do all things necessary for a civil organization. These acts have all been passed during the last four years.

The constitutionality of the bonds to be issued have been assailed, but were affirmed and sustained by the Supreme Court. Since then, action under the district laws has been progressing quite rapidly. Some twenty districts had been organized at the time your committee was in California. The bonds of several had been successfully negotiated. Since then, at least ten more have been set up in operation, the larger portion being in southern California. The amount of bonds involved ranged from $6,500 in a San Bernardino district to $3,000,000 in the district now forming in Fresno County. The area so far included will be over 3,500,000 acres. Probably one-sixth of this area is already irrigated.

Under the present system every water user first pays a royalty for the right to use of about $2,500, and thereafter an annual rental of $2.50 per acre. In condemning a ditch system, the district may under the law regard the royalties paid as compensation, to their full extent, of the original outlay. They will pay, therefore, for the ditches on the basis of their annual rental values. The proposed new works will have no charges to meet other than those legally established for the payment of interest, the repayment of the bonds, and maintenance of the district irrigation works.

As the area of reclamation grows larger each year, the annual taxation must necessarily grow much smaller to each individual. The cost under private or corporative ditch systems will certainly exceed at the end of twenty-one years that of the district system, by the entire amount of royalty the private enterprises would have exacted. And when the district debt should be paid off, the small annual cost for maintenance and repairs would be all that irrigators would have to bear.

EFFECTS OF IRRIGATION ON HEALTH.

There is another and very important question to be considered, and that is as to the effect of irrigation on the general health. In California considerable attention has been paid to this subject, and in 1884 a report on the subject was made by the State board of health. There are conflicting opinions in the report made by the board. In certain counties, as Ventura, Santa Barbara, San Bernardino, San Diego, irrigation has been employed for over a century, and the absence of malarial disease is noted, as well where irrigation is practised as where it is not.

Other portions of California show a marked increase of malarial fever where irrigation is practiced. It is not difficult to discover the reasons for this. In Los Angeles and other valleys in extreme southern California, where the soil is, as a rule, sandy or gravelly loam of unknown depth, the water used in irrigating sinks into the ground or (on sloping surface) drains off immediately. It does not remain to saturate the soil unless there be a stratum of clay (hardpan) near the surface. In such sections of the country there is almost entire freedom from malarial diseases. Along the bottom lands of rivers, and where the slope is insufficient to insure good drainage, or where the soil is saturated constantly, the case is different, and there are intermittent and remittent fevers during the warmer seasons of the year. The fact that the people living in these low, wet sections of country are dependent upon impure or surface water for drinking and domestic purposes aggravates the difficulty, for it has been demonstrated that people living in a fever-and-ague country are tolerably exempt from the disease if they drink only pure water.

From all portions of California letters from medical practitioners and other residents are in singular accord in saying that irrigation, when properly managed, does not produce any increase of malarial diseases.

IRRIGATION AND FRUIT RAISING.

The State Board of Trade reported in a careful paper that:

> The peculiar productions of California is another reason why irrigation will soon be a great feature in our agriculture. California is situated quite differently from any other Pacific coast State or Territory. Indeed, many of the productions of its soil are peculiar to it. For instance, there are planted in California, according to authentic data, 50,000 acres in orange and lemon trees; all these must be irrigated. Last year there were shipped East for sale 1,850 car-loads of oranges and lemons, and about 600 car-loads were consumed at home. There are over 20,000 acres of olive trees planted in California. Most of these are not bearing; some of them are; but enough are in bearing to show that this remarkable fruit grows here with wonderful luxuriance and bears abundantly. The olive thrives nowhere else in the United States. Last year there were produced in this State 3,400 cases of olive oil, and of the very best quality. There are 140,000 acres of land now planted in grape-vines in the State of California; and for the year 1888 there were produced 18,000,000 gallons of wine, 20,500,000 pounds of raisins, and 1,000,000 pounds of dried grapes. These vines are the European varieties, which will not grow where the ground freezes; and they are not successfully cultivated in any other part of the United States. Both our wines and raisins are successfully competing with European productions. There are about 1,000,000 prune trees growing in California, outside of the acreage planted during the winter of 1888-'89. This most-needed fruit is not produced in the United States except on the Pacific coast.
>
> In 1888 California produced 7,000,000 pounds of prunes, and it will be observed that there were imported into the United States for the same year, for consumption in America, over 70,000,000 pounds. In a very short time California will be able to supply the American market. There are 300,000 fig trees planted in California, and the figs produced here are of the very best quality. The trees grow luxuriantly and thrive well. It must be admitted that it is of infinite importance to our country to encourage the production at home of all these articles which otherwise we would be compelled to import.
>
> In this connection it may be added that California is a great nut-producing country; the almond grows well and produces well. There are now over 25,000 acres of land planted in almond trees, and this acreage is yearly increasing. In 1888 California produced 180,000 pounds of almonds. The so-called English walnut is also a most valuable California nut, and grows well in nearly all sections of the State where the soil is deep or irrigation possible. No mention is made of the peach, the cherry, the pear, the apricot, the nectarine, the plum, or the apple. All these fruits are grown in California in such abundance that the mention of them seems unnecessary. Add to these fruits the whole berry family, conspicuous among them the strawberry, the blackberry, and the raspberry, and we may well observe the unlimited capabilities of this State for fruit culture.

Its report presents the following facts, among others:

IS IRRIGATION ADVANTAGEOUS?

The advantage of irrigation is twofold: first, the water is applied at a time when it will do the most good, and when the ground is in such a condition that the grain or the fruit trees will get the full benefit of all the water that is run upon the land; and second, where irrigation is practiced there are no droughts. In countries where there is ordinarily an ample rain-fall, the crops often fail by reason of droughts. This arises from the fact that the rain falls in vast quantities, but at unpropitious times, when it does little or no good to the crops.

In California, from about the middle of May until the last of October, we have no rains. During this period grain is harvested.

The use of water is often more valuable for fruit growing than for small grains. We doubt whether the wheat fields of California will ever be irrigated, because fruit is more valuable and the irrigation of orchards is more readily accomplished than the irrigation of the small grains; and because, as a rule, in the great wheat-producing portions of California irrigation for the purpose of producing one crop of cereals is not necessary. But California is especially a fruit-growing country. Its adaptability to almost all kinds of fruit is peculiar. Perhaps no country in the world is its equal; and in some of the great interior valleys of the State, and also in the foot-hill counties, successful fruit growing can be made certain only by irrigation. With the orange and lemon irrigation is a necessity. Where orchards require irrigation it has been proved that to sustain the trees in their growth and fructification, water need not be put upon the land more than from three to five times during the summer and fall months. The practice is to run water in small ditches between the rows of trees through the orchard about once a month, commencing in June and ending in September. Then immediately after irrigating the ground, by allowing the water to flow through these small ditches, the practice is to put in the cultivator, stir up the ground anew, so that the evaporation will not be rapid, and the ground will not settle down and become hard. The land thus remains friable, and the trees grow with great rapidity.

The orchards and vineyards in the coast counties and in central and northern California have hitherto never been irrigated. Where the size of the grape is an especial and important factor, like in the making of raisins, the irrigation of the vines is advantageous, and especially where the vineyard is planted in very hot and dry situations, like at Fresno and Merced. Up to this time no grape vines nor orchards have been irrigated in any of the counties of Santa Clara, Alameda, Contra Costa, Solano, Sonoma, Marin, or Napa, and the fruit trees and the vines grow there with great luxuriance and produce abundantly; and yet in each of these counties vegetables and the smaller fruits, like strawberries, are now irrigated during some of the summer months.

THE AMOUNT OF WATER NECESSARY.

There will not be required the same amount of water for successful irrigation in California as is used in India. In India it requires about 1 cubic foot of water running every second to irrigate 200 acres of land to produce cereals. In Granada, Spain, where cereals are produced, 1 cubic foot of water running per second irrigates about 250 acres.

One inch of water running continually irrigates in southern California about 10 acres. Even less than this amount would be required in portions of central and northern California.

THE RESULTS OF IRRIGATION.

Los Angeles and San Bernardino Counties are conspicuous illustrations of what irrigation can accomplish. Nothing can picture the change which has there been made by means of irrigation. A great plain which once looked like a desert is now covered with beautiful homes, surrounded with orange orchards and vineyards, dotted with towns and cities, which have grown up everywhere as if by magic. The population has more than quadrupled in a single decade. Lands which sold ten years ago at from $5 to $25 per acre now sell at from $100 to $1,000 per acre, and these prices seem to be fixed from what the lands actually produce. Nor is this condition of things peculiar only to southern California. In Placer County water has for some years been used for the irrigation of orchards and vineyards there planted. It is impossible to describe the change thus created. Orchards of every variety of fruits, from the orange and lemon to the apple, and vineyards of every rare variety of grape, and nuts of all known varieties grown in semi-tropical climates, and the fig and the olive, all seem to flourish in the foot-hills of Placer County; nor does the result in Placer County seem to be peculiar to that locality, for everywhere in the foot-hills of the

Sierra Nevadas, where irrigation has been introduced, the result has been equally surprising.

The foot-hill country about Oroville, in the county of Butte, where water has been introduced, is no less conspicuous for its luxuriant tree-growth. Within the last four years 1,500 acres of orange orchards have been planted, and these trees seem to be thriving well. The oranges are rich in color, luscious in taste, and attractive as to size. This is mentioned only to show the effect of irrigation upon both the foot-hill and valley lands of the State of California.

More marvelous still is that section of country lying about half-way between the extreme northern and southern part of the State. Within the past few years a town has been built there, which has a population of over 10,000; the surrounding country is cultivated in everything the farm can produce. Indeed, Fresno County is to-day the great raisin-growing center of the State, and nearly every variety of fruit grows abundantly. There a beautiful orchard stands side by side with an alfalfa or grain field. Homes are literally hid away by the remarkable ornamental tree-growth which irrigation has caused. Ten years ago the lands of Fresno sold at from $3 to $20 per acre; now the same land with water on it sells at from $75 to $750 per acre. This is all due to irrigation. Kern County is another conspicuous land mark on the road to successful irrigation; more than 80,000 acres of land is being irrigated in that county. The production is generally alfalfa.

Everywhere in California during the summer months garden vegetables are raised by irrigation. In the fall, winter, and spring months in most parts of the State they require no irrigation, except such as they get from the natural rain-fall. So with strawberries; this fruit is universally irrigated. In Santa Clara County alone it is claimed there are 1,500 acres of land cultivated in berries, all of which are irrigated; and that there are over 500 acres cultivated in garden vegetables, which are also irrigated. Even in northern counties like Napa, where the annual rain-fall is almost three times as great as in some parts of southern California, strawberries, other small berries, and garden vegetables during the summer months are universally irrigated.

IRRIGABLE AND STORAGE AREAS.

Large areas of plain or bench lands, lying above the bottom lands of the river, are to be found in Shatsa, Tehama, Butte, Colusa, and other Counties. They are all within reach of the water flowing down the Sacramento River and its lateral tributaries. Most of the streams emptying into the Sacramento from the Coast Range sink and disappear during the summer not far below where they debouch from the mountains into the open country; but at their sources there are large quantities of water that can be stored or impounded in the reservoir-sites that are available.

The irrigable lands of Lassen County, lying about 1,000 feet below these sources of water, are not far from 500,000 acres; and east of these lands, in the State of Nevada, is an area of like extent. The lands are rich, sandy loam, productive with water, but comparatively useless without. The climate of Honey Lake Valley is most delightful, being free from excessive heat and not subject to very low temperatures. Here is a region of nearly or quite 1,000,000 acres of public lands that can not now be settled upon, but are nevertheless capable of sustaining a arge population. A rough calculation shows that in Eagle Lake there is stored enough water to irrigate 500,000 acres of land; and at the head of Susan River comparatively cheap reservoir sites are available to store water sufficient for a half million acres more. North of this region lies Madelin Plains, a large area of good lands if irrigated. In Modoc County like areas are lying idle and useless, yet are capable of high cultivation and of sustaining a large population.

Inyo County, Cal., is especially adapted to irrigation, particularly that part of it known as Owens Valley. From Olancha to the head of Round Valley is 100 miles; the whole of this distance, a strip of country from 4 to 6 miles in width, is susceptible of irrigation. There are from 300,000 to 400,000 acres of land of unsurpassed fertility which are utterly worthless without the use of water. It is claimed by experienced engineers that the Owens River carries on an average, and during the summer months, water enough to place at least a surface depth of 15 inches upon an area of 300,000 acres of land, and this without preparing catchment reservoirs. A large portion of this country is still a part of the public domain. Less than 12,000 acres of land are now cultivated in Owens Valley.

In the extreme southern portions of California there is ample opportunity for storage on a large scale. There is a difference of opinion among engineers. Some think there are many basins and cañons in the mountains which are adapted to the purpose, and others think these, on most streams, are wanting. Most, however, agree that the bench lands furnish abundant opportunities for the construction of reservoirs. There are a number of reservoirs of both kinds finished and in process of construction, of capacity varying from a few thousand to a billion gallons. One on Mormon Creek, in the rim of the San Fernando Basin, is of more than the latter capacity.

The number of acres of good land which require irrigation are, south of the mountains, according to the State engineer's estimate, 460,900. North of the Sierra Madre range, Los Angeles County shares with Kern and San Bernardino in the great Mojave desert, so called. This desolate region contains many thousand square miles. In these three counties one-half of this is probably arid beyond redemption; one-half of the remainder is too rough and mountainous to be valuable for cultivation, but the remainder is mostly highly fertile soil, lying favorably for the application of water. Of this vast territory, Los Angeles County possesses 250,000 acres, which can be made to comfortably sustain a population of 100,000 people.

It is stated that the lowest summer flow of the Mojave River is about 5,000 inches. The average flow for six months in the year, the winter and spring months, is from 20,000 to 30,000 inches; during May, June, and July more than 10,000, and for the rest of the season more than 5,000 inches. Of this the Hesperia Land and Water Company has filed a claim of 5,000 inches.

The land is mostly Government land, and the profits thereon would pay for enormous and elaborate works. Big and Little Rock Creeks, which debouch upon the desert plain at higher elevation, west of the Mojave River, are wholly within Los Angeles County. Their flow in winter is thousands of inches, and in summer is sufficient, as at present handled, to irrigate several hundred acres. Facilities for storage on these creeks are as abundant as on the Mojave. The land below is still owned, for the most part, by the Government. The universal testimony is that it is as fertile as the best. It is covered with grass and flowers during several months of the year, and is capable, under irrigation, of producing the most luxuriant and profitable crops. Artesian-well boring has proved successful in places on the desert, but the expense is of course greater than elsewhere. The region is one of the most healthful on the globe. Its hot, dry atmosphere is found congenial to many people. It is especially adapted to the production of certain crops, as the fig and raisin grape. It produces in some places as fine wheat as is raised anywhere, but to become habitable for any more than a few scattered families or small communities, it must have water to save its crops in summer. Value of irrigable land, $50 per acre; non-irrigable land, $1.15 per acre; the number of artesian wells in the region, seven, with an average depth of 340 feet and average flow of 12 inches. The counties of Los Angeles and Orange have an area of 4,812 square miles, or 3,079,680 acres. Their population is fully 150,000 souls. Without irrigation not one-quarter of this number would be living there; and "this in spite of the fact that those two counties produce more than one-half of the corn of the State almost altogether without irrigation; that there are nearly 90,000 acres of good land that require no irrigation."

The land now irrigated is about 150,000 acres, and this is the basis of maintenance of 113,000 people. Theoretically, no increase of this population is wanted without a corresponding increase of irrigated lands. Factories and mineral developments, travel and transportation by sea and land, and the healthfulness and delightfulness of the climate, would add to the population; but the cost of living would be increased in proportion to growth, the homes of the poor would no longer be those of people who control their own destinies; and this would become a rich man's paradise—a thing not to be desired.

Ten years ago the population of the counties was little over 30,000. Fifteen years ago the land on which Pasadena now stands was held at $7 per acre; in seven years it was valued and sold in large quantities at from $500 to $1,000 per acre. This was for orchards—not city lots—orchards made possible only by a supply of moisture for the roots of the trees during the long arid season of the year. So with the whole of the great foot-hill region along the base of the Sierra Madre range from Tejunga and Crescenda Cañada on the west through Altadena, Sierra Madre, Lamanda Park, Santa Anita, Monrovia, Duarte, Ayusa, Glendora, Alosta, San Dimas, Lordsburg, Cucamonga, Rialto, Redlands, and over the San Gorgonio Pass into the desert at Indio, and again at Riverside and Arlington, and places too numerous to mention. The growth has been proportionate to the extent to which irrigation has been carried. The region mentioned was almost worthless even for grazing purposes, and was as incapable of sustaining a population as the Mojave Desert itself. Now visit it and you will find it the most charming region and the most valuable land in all California, or in the United States for that matter.

GROWTH OF ENTERPRISE AND VALUES.

In Fresno County there are 100,000 acres of land now irrigated. This estimate is made by Mr. George Manuel, a well-known civil engineer, but he adds:

"It is somewhat difficult to draw the line between irrigated and unirrigated lands, for the reason that the effects of irrigation by filling up the country affect and render fertile to a great extent lands lying contiguous to irrigated lands, but not themselves subjected to irrigation by the usual methods of application. Of this latter class of lands," says he, "there are about 200,000 acres."

Thus it will be seen that the 200,000 acres are an area double in extent of that which is actually irrigated, and is reaping the benefits without being subjected to any of the burdens of irrigation. Irrigation in Fresno County has heretofore been carried on wholly by the private canal system. It is a voluntary matter by this plan with each landowner whether or not he will contribute anything towards the expense incident to the irrigation of lands. His lands may be surrounded by irrigated lands, and thus in a short time they become sufficiently irrigated by percolation; but he may and does decline to buy water where he can get it by absorption without. By the district plan this iniquity is overcome; and every man who owns land that will be benefited is compelled to contribute his portion of the expense incident to the system, and gets in return all the water he may require.

The following is the estimate made by Mr. Manuel of the amount of land in Fresno County which is now not irrigated, but which is irrigable:

	Acres.
(1) In Madera irrigation district, about	300,000
(2) Under Chowchilla Canal, excluding about 5,000 acres already irrigated.	60,000
(3) Land lying above or east of Madera district, but which can be irrigated by a branch of the main canal of said district (in Fresno County)	87,600
(4) Land lying above water in main canal of Madera district, but which is susceptible of irrigation by a system of storage reservoirs	38,400
(5) Land lying between San Joaquin and Kings Rivers, excluding about 60,000 acres already irrigated, and which can be irrigated by existing works or their extensions	684,960
(6) Land lying above or east of Enterprise Canal, but which can be covered by storage reservoirs or branch canal taken out high up in the mountains	40,000
(7) On west side of Fresno Slough, below Hall survey in Fresno County, which can be covered with extensive irrigation works	113,000
(8) In Sunset irrigation district above Hall survey, proposed to be irrigated by a canal having levees 35 feet high at highest point, and about 15 miles long, and which lie above Hall survey	190,000
(9) Between the 240 and 300 feet contour line on State engineer's map, which can be irrigated by canal taken from Kern River, or by water pumped by water power as proposed by Sunset district in Fresno County	190,000
(10) Land lying above the 300 feet grade line in Fresno County on west side, which can only be irrigated by storage reservoirs on the streams flowing from the Coast Range	293,000
Total	1,996,960

Mr. Manual states further that—

In 1870, in township 14 south, range 20 east, sections 1 to 5, assessed to W. S. Chapman, at $1.01 per acre; section 36, at $1.13 per acre; that made an assessed valuation of that township, in 1870, of a little over $25,500 in round figures. In 1880 the Bank of California tract, a portion of these twelve sections, at $4 an acre, and Bank of California tract, 240 acres, at $5 per acre. C. A. Towne, section 2, adjoining Fresno City, at $5 per acre. C. H. Hoffman, section 12, near Fresno, at $5 per acre. E. Jansen, six sections near Fresno City, at $4 per acre. In 1888, A. T. Covell, in Washington Colony, 5 miles from Fresno, 60 acres, at $150 per acre. Sections 1 and 2 and 11 and 12 at $250 to $300 per acre, $250 per acre being about the average for unimproved land. And this increase in the value of land is due to irrigation. It is the same land exactly, only in different years, as irrigation has progressed.

Sections 6 and 7, at $100 per acre; section 19, at $75 per acre; sections 5 to 8, unimproved, and from one-half to 1 mile from the city of Fresno, at $125 and $200 per acre; sections 17, 18, and 19, averaging $85 an acre, and sections 23, 24, 25, and 26, at $75 per acre. That is the valuation of that township. The first assessment was $25,500 in round numbers, and the last assessment of the city, $6,800,000. And the total valuation of that township is probably in the neighborhood of $9,000,000. Concerning the value of irrigation, I know of one canal that was said to cost in the neighborhood of $50,000. The first year after its inception the increased value of the real estate along the line of the canal was $640,000—land that could before have been bought at $2.50 per acre had increased in value sufficient to make that valuation. So I could give other instances, but I suppose that would be sufficient.

Mr. Thomas Hughes, well known as a real estate operator, also testified that—

In 1881 I purchased 7,000 acres of land adjoining the town of Fresno, agreeing to pay $40,000, and having 6 months to make the first payment of $5,000. I immediately had circulars printed, offering to sell land, with water for irrigation, to parties who would move on the land and improve in trees and vines, without any cash payment. In this way I soon sold the most of this tract, and would borrow on my note with these mortgage notes as collateral security, getting about 50 cents advance on the dollar. I sold the land at prices ranging from $40 to $75 per acre. This gave me a surplus of money to pay what I was owing on the land, and money to make a small payment on the purchase of other lands, which I continued to do from year to year, until I was myself $350,000 in debt, and had mortgage notes due me to the amount of nearly $500,000 for lands in most cases sold on a credit of one, two, and three years, with interest at 10 per cent., payable half yearly. The settlers have all made their places worth to-day from $200 to $1,000 per acre, and all have paid me in full. I have sold thousands of acres of land on these terms, and I have never been compelled to foreclose a mortgage in Fresno County. Men who will work can settle on irrigated land, pay their 10 per cent. interest, improve the land, and pay for their land at prices ranging from $50 to $125 per acre inside of four years. And that, too, on land that before the irrigation system was started could not be sold for more than from $1 to $5 per acre, according to location.

In Tulare County much progress has been made in the work of irrigation. The one criticism to be made on the work in that section is that it is fragmentary and lacks uniformity and systematic methods. Irrigation is consequently patchwork, but enough has been done to demonstrate the miraculous power of irrigation in the San Joaquin Valley.

Mr. P. Y. Baker, civil engineer, for many years devoted to the work, says: "There are about 15,000 acres irrigated in this county, and 950,000 acres not irrigated. There are about 250,000 practically useless without irrigation. Of the above 950,000 there are perhaps 700,000 that produce some crops without irrigation, but very little of it produces fair crops. That is to say, one year with another, the average would be so low that it would be a serious question of making a bare living on most of it. Experience has shown that the proximity of irrigation has added much to the productiveness of non-irrigated lands."

In Merced County provision has been made whereby a considerable area of lands may be irrigated; but the acreage actually subjected to irrigation is small. The Crocker Canal, which is said to have cost $1,500,000, is situated in this county, and will eventually be applied to a large area. The area of the plain lands which may be profitably irrigated is large. So far as irrigation has become an accomplished fact in the San Joaquin Valley, it has been done through private enterprise. Under the district irrigation law of 1887 a number of irrigation districts have been organized, and by this means the irrigated area will soon be rapidly extended. Twelve irrigation districts are reported as organized or in process of organization within the valley of the San Joaquin. The total acreage involved is estimated at 2,000,000; the total amount of the bonds to be issued will not be less than $10,000,000. The area of the following irrigation districts can be given with accuracy:

Modesto	acres..	108,000
Turlock	do...	176,000

Total area San Joaquin Valley		1,767,000

The total area irrigated in the same section was given by State Engineer in 1885, at 251,140 acres. This area has certainly increased one-fourth, and would therefore be not less than 313,670 acres. It is probably nearer 350,000.

LOS ANGELES COUNTY.

The irrigable portions of Los Angeles County are embraced in the San Gabriel and San Fernando Valleys and the coast plain region. The San Gabriel Valley is 23 miles in length, east and west, 11 miles in width, north and south, with a broad outlet somewhat west of the middle point on its southern side. It is but little less well-defined as a basin than that of San Bernardino. At the lowest point on the higher side of the valley, next the mountain base, 11 miles north and 2 miles east, the elevations range from 625 to 675 feet. At the extreme northwest corner they are between 1,500 and 1,700 feet, and at the other extremity of the valley, next the mountain's base, the plain is 1,000 to 1,100 feet above the sea.

Together with its mountain and hill-side catchment areas the San Gabriel Valley embraces a territory about 560 square miles in extent. The mesa, benches, plains, washes, and bottoms composing the valley itself cover nearly 200 square miles, or about 123,000 acres. Of this amount about 92,500 acres are highly cultivable and productive lands, but requiring irrigation.

The San Fernando Valley occupies the western portion of the Southern California basin. It contains about 570 square miles. Of this area there about 100,000 acres of really good irrigable lands. The coast plain embraces an area of 1,472 square miles. Of the total, leaving out hills, marshes, wet land, and 68,000 acres requiring irrigation, there are about 270,000 acres fit for cultivation by irrigation. It is all below 500 feet in elevation.

The rule as to distribution of rain-fall, as affected by the mountain ranges, is emphasized in Los Angeles; the heavy down-pour is on the slopes of, and on the plains and bench-lands at the base of, the ridges, on the side next the direction from which the storm clouds are brought.

On the coast plain and elsewhere on the lower elevation the down-pour reaches about 15 inches per annum. In the San Fernando Valley, from other causes, it falls to about 11 inches. At the base of these mountains it rises to 15 again, and at Ravenna it falls to less than 11 inches, though the elevation is 2,300 feet above the sea. But as the base of Sierra Madre is reached, the precipitation reaches 22 inches, though the elevation is but 700 feet. On the mountain bench-lands the rain-fall is from 50 to 100 per cent. greater in the valley, but 10 miles distant and but 600 feet lower.

Of the irrigable portions of this county, the San Fernando Valley and the coast plain are materially the driest sections, and the bench-lands and mesas, at the bases of the Cahuenga and the Sierra Madre, receive much the greatest rain-fall. San Gabriel Valley, as a whole, probably receives 50 per cent. greater rain-fall than does the San Fernando, and 80 to 90 per cent. more than does the valley of San Bernardino. The reasons for these differences are found in the following facts: San Gabriel Valley has no high mountain range in front of it, and has a high range immediately back of it. San Bernardino Valley, notwithstanding the fact of the higher range behind it, has also quite a high range in front. San Fernando Valley has a moderately high range in front of it, and only a moderately high range behind it for more than half its length.

The streams all lose their waters in the underlying gravels, within a few miles of their cañon mouths, during fully eight to ten months (including the irrigation months) of almost every year. All but two or three of the larger cañon streams do not, naturally, even bring their waters outside the cañon mouths, for six months of almost every year. The waters are lost in bowlders and gravels, but they reappear below in the springs and *cienagas* of the Los Angeles Valley, or in those of the San Gabriel basin. There are two classes of streams, then, serving irrigation in this region—those which have their independent mountain drainage areas, and come to the interior valley through deep gorges or cañons, and then sink; and those which rise at the outlets of the three main divisions of the interior valley, namely, the Los Angeles, Lower San Gabriel, and Lower Santa Ana Rivers.

There are eleven principal groups or systems of irrigation, the San Gabriel and San Fernando basins being again subdivided into as many more. The description of San Bernardino works will serve largely for those of Los Angeles County. The artesian-well groups are numerous, and their economic use is an entire and extended success. Sub-irrigation by iron and cement conduits is a great feature, four systems alone using 240,013 feet, of which 3,005 feet are of iron piping. There are also 3,607 feet of cement canals. The cost was $275,000, $90,000 of which was for well-boring and water development. These systems belong to the Pomona group of fruit colonies. In practice, a fixed and uniform rate of 10 cents per hour for a run of water is charged, as a *zanjero's* fee, each time a head of water is turned on to an irrigator. The "heads" used in irrigation are 30, 45, and 60 inches in volume, but the rate charged is the same for all, so that the double volume afforded by the 60-inch head costs no more than that afforded by the head of 30 inches, for the twenty-four hours. The actual cost of water to the irrigators per acre ranges between 72 cents and $1.92, and averages about $1.30 per year.

There are in Los Angeles County a large number of settlements made on the colony plan, and a more considerable area occupied by large and small ranches, vineyards, and orange groves. The water system, serving the city and for domestic as well as neighborhood and irrigation use, is as typical as anything in the land, being based on the old Spanish-Indian community plan, as modified by modern use and growth. The *zanjas* have a total service and length as follows:

	High and low service.	
	Feet.	Miles.
Open earth ditches	140, 135	26. 5
Cement pipes or conduit	91, 490	17. 3
Iron pipe	28, 836	5. 5
Wooden flume and tunnel	15, 900	3. 0
Total	276, 361	52. 66

This summary shows that the total length of conduits maintained by the city is 52.3 miles, of which 25.8 miles, or nearly 50 per cent., consists of tight conduits—wooden flumes, cement and iron pipe, cement or masonry-lined canals, brick culvert, etc.—and the balance consists of open canal and ditches of various kinds and sizes.

There are 40 miles of ditches outside this system, but receiving their water supply from the city zanjas, making in all over 93 miles of conduit, connecting with as many more miles of private distributory ditches and pipes. The cost has been during the past fourteen years about $300,000.

The irrigation system of Los Angeles is under the direct control of the city council, from the heads of the zanjas on the river to the southern limits of the city, and from there on the distribution is managed by several associations of outside irrigators.

The council appoints a general zanjero, or ditch overseer, and assistants, fixes the rates for sale of water, orders all zanja improvements that are made within the city, and maintains entire control over diversion from the river. In times past the council has apportioned the water to the land within city limits at the rate of an irrigating head for twenty-four hours to one acre for every thirty days. This was when the acreage irrigated inside the city limits was greater than it now is. This city allotment is now, however, a dead letter, as the inside irrigators have more than they require, and the council has no concern for distribution of the water after it leaves the corporation limits. Every individual irrigator whose lands are inside the city bounds is allowed all the water he wishes to buy and pay for without restriction, and the surplus waters are sold to the outside associations.

Outside the city limits the irrigators are organized in regularly defined districts on the extension of each zanja. These districts abut on the city, and when organized were considered to embrace all lands which could be reached by the spare water of the river. Some of them have been much extended, however, and in one or two instances secondary districts subject to and buying water from the primary districts are found adjoining the latter. With the improvement of the zanjas and the diminution of cultivation within the city the irrigable area has extended year by year, and is now carried even beyond the secondary outside districts. The outside organizations are incorporated associations of irrigators, which elect officers, are governed by sets of by-laws, and appoint zanjeros, whose duty it is to purchase surplus water of the city and sell it to the irrigators, each of his own district, at a premium fixed by the association, which constitutes its compensation.

Water is sold by the irrigating head in measure of time. The rates, always subject to change, are at present in the city $3 per head per day (sunrise to sunset); $2 per head for half day (sunrise to noon, or noon to sunset), and 50 cents per hour. Current rates charged the outside districts by the city are $5 per head per day, $3 per night. Single hour permits are not sold outside. These rates are 50 per cent. higher than they were two years ago. In 1880 the city rates were per day $2; half day, $1.25; night, $1.50. In 1873 they were $1.75 per day, $1.25 per half day; $1 per night, inside city limits. Outside they were $3 per day; $2 per night. In 1870 in the city they were $1.50 per day and $1 per night from March 1 to October 1. After the latter date 75 cents per day and free at night.

The area irrigated under this system is about 12,000 acres, of which nearly 3,000 is within the city limits.

Engineer Hall mentions in his last report 250 different systems of irrigation works within the three southern counties of California; also 18 different artesian water and well basins, the total acreage of which is large.

SAN BERNARDINO COUNTY.

Mounts San Bernardino and Grayback are the culminating points in the topography of southern California. From them, trending southeast, start the San Diego ranges, which enter Mexican territory. Extending west, the Sierra Madre ranges reach away over a hundred miles through Los Angeles and into Ventura County. Standing at the meeting of these masses the San Bernardino peaks are the highest and most commanding objects in the landscape, and play a very important part in modifying local climatic phenomena and regulating irrigation water supply.

From the northwestern end of the San Diego range, or plateau, begins what is known collectively as the Coast Range, extending northward into and beyond Los Angeles County. Its face to the sea is a sloping plain or mesa. East of this range and between it and the Sierra Madre lies the smaller counterpart of the great San Joaquin Valley to the north of it. From the coast to the San Bernardino Peak westward is a distance of 110 miles. Broken by two small, low groupings, it comprises the most valuable fruit region of the State. Within this area will be found at least 100 colony towns and villages; the growing and prosperous city of Los Angeles, and a population of over 250,000 persons, all of whose prosperity depend upon irrigation. In Los Angeles County the coastwise mesa becomes a broad alluvial plain. Engineer Hall, in his volume on irrigation in southern California, says:

> North from the Sierra Madre chain stretches away to the Sierra Nevada mountains, a distance of over 50 miles, and from the Colorado River on the east to the Santa Barbara Mountains on the west the desert plain of the Mojave, comprising an area of 15,000 to 16,000 square miles. On this broad plateau there are extensive tracts of rich soil; but from the want of rain they are barren, and from the absence of water supply they are, except in very limited localities, non-irrigable. The Mojave, then, is not, save in a very much restricted sense, a part of the irrigation field present or prospective, although locally irrigation flourishes there and many small utilizations of water remain yet to be carried out.

It is the Sierra Madre range of southern California which, passing through Los Angeles and San Bernardino counties, constitutes a mountain wall, that, intercepting ocean breezes and storm clouds, precipitates their moisture upon high and rugged peaks, thereby regulating climate and making possible that high degree of cultivation which is necessary for successful horticulture.

The effect of an intercepting mountain range upon rain-fall is most distinctly marked in this region. The San Bernardino section offers no gradations as in San Diego. The clouds drifting inland from the sea are broken on the summits of the Sierra Madre and precipitate their contents upon its bald slope. They cover the crest with snow, and send great rains down the western slopes in heavy torrents. The valley below will have a rain-fall of barely 8 inches per annum. The mountain peaks and spurs above will receive from 70 to 100 inches in the same period. The slopes are exceedingly steep.

The accumulation of vegetable molds and soils, which are recognized as water-holding, are limited in extent. In an earlier geological era the rain-fall was immensely greater. Vast mountain torrents in those days poured through the cañon, carrying great masses of bowlders before them. The operation of the forces thus created have made deep bed-rock cuttings that are now filled with masses of broken matter. Into these flow and disappear the waters that pour from the mountains above. In this wise the artesian waters of the San Bernardino basin are collected.

The Santa Ana River, with an independent mountain area drainage of 220 square miles, is the main surface drain of this irrigable region and also its chief irrigation feeder. There are some twenty smaller and tributary creeks, cañons, or washes. In addition to these drainage areas the northern face of the San Bernardino range is drained by the Mohave River. The basin slope from east to west is about 26 miles in length, and comprises 120 square miles in all. Its future importance in irrigation is considered large. At present it is lost in the sandy waste 40 miles from its source. Engineer Hall classifies the San Bernardino lands as follows:

> (1) The wet and marshy lands of the San Bernardino and Rincorn artesian basins, and the Chino; (2) the moist and semi-moist lands bordering the wet lands of the Rincon on the north, and bordering those of the San Bernardino on the north and east; (3) the moist bottom-lands bordering the Santa Ana River in its course through the Jurupa from the upper to the lower basin; (4) then, going to the other extreme,

the bone-dry red mesa lands, which fringe the entire valley more or less completely; (5) the bowlder and cobble-filled alluvions, which form the ancient dumps of the cañon creeks, and which, along the base of the main mountain range, to a great extent take the place of the red mesa lands; (6) the intermediate plains—dry, sandy, frequently gravelly, and with broad "washes" in parts, but in others with fine, light, rich, and deep soils.

The topographical features of the basin, with its great slopes in the ground surface ranging from 30 to 120 feet per mile, renders impossible any system of irrigation by "checks," such as is practiced in the San Joaquin Valley. It also compels the grouping of irrigation works and areas, deriving their supplies from limited and distinct sources. Three of these groups, embracing a large number of small works, obtain their supplies by diversions from the Santa Ana River or its main tributaries. Four other groups are fed from mountain cañons, the waters in which are derived mainly from subsoil supplies in the strata already described. Other groups obtain water by means of artesian wells, by tunnels driven into the mountain and securing thereby the drainage waters by lifting the sub-water of the cienagos or wet plains, or by other sub-dam works, raising to the surface supplies that would otherwise be lost. It is estimated that the great storage project of San Bernardino County, the Bear Valley reservoir, will very materially change the irrigation possibilities, or greatly enlarge the area of land under cultivation.

The value of water has enormously increased. The North Fork Water Company, which is under guaranty by the Bear Valley Reservoir Company, sold in 1865 at the rate of $30 per share, the water being valued at $18 per inch. In 1880 the value per share was $50, and that of water $26.40 per inch. In 1885 the value per inch of water was $360, and in 1888 $720. In another enterprise $40,000 is reported to have been paid for perpetual right to one cubic inch of water. The South Fork Canal valuation is given at $6 per miner's inch in 1872, and at $615 in 1887.

The different sources of supply, and the character and extent of areas served, compel as great a variety in the systems of distribution. One of the most notable of these systems is that made by tunneling into the mountain cañon walls and securing the drainage waters that pass through them. At Redlands, one tunnel delivers about 30 miner's inches, another about 130. The Ontario Colony enterprise, whose engineers, the Chaffee Bros., have since become known all over the world by their connection with great Australian projects, is the most famous of these tunnel works.

The water company at Ontario, after conserving all the surface supply by means of cemented canals and underground pipe-line, have driven a tunnel into the gravel and bowlders of the cañon bed a distance of 2,850 feet. Nowhere in the world is the duty of water so high as at Ontario. The supply is less than 800 miner's inches per annum, of which the tunnel will furnish from 50 to 60. The whole distribution is conducted through cement pipes. The work of distribution is in charge of a *zanjero*, or watermaster, who delivers water to each irrigator in heads of thirty inches for twenty-four hours each thirty days, for each ten acres owned, which is equivalent to a continuous flow of one inch to ten acres. The secretary of the company and the *zanjero* are the only regularly paid employés, but laborers are at times employed to work under the *zanjero's* direction in caring for and repairing the works. The cost of assessment for maintenence has not exceeded, so far, more than 70 cents per acre. The duty of water is claimed to range as high as one inch to ten acres; it is probably about one inch for seven acres.

The Riverside Colony enterprise and its associates are the most prominent and best known of the fruit colonies in southern California. The works of the Riverside Water Company consist of three main canals and diversions, an extended irrigation distribution system, and a main pipe-line, and branches for the delivery of water, chiefly for domestic purposes.

The supplies are derived from the Santa Ana River and Warm Creek, and from an extensive system of artesian wells. The canal works are thoroughly constructed, provided with 2,400 feet of main flume, dams, head-gates, waste-gates, regulators, measuring-boxes, etc., having a total length of 33 miles of main canals and 50 of laterals. The area of Riverside proper is about 7,000 acres. With other and adjoining enterprises, the total area in the Riverside group will be 26,000 acres. It is the largest single orange-growing section in the State, and is second only to Fresno for raisin vineyards. In 1870 the land was assessed at 75 cents per acre; every acre of it will now average from $800 to $1,000. Originally begun as a land colony or co-operative enterprise, the projectors designed to keep the water supply separate as a continued source of income. Great dissatisfaction followed that plan. The land and water supply now go together. The entire cost of works within the old colony bounds, including legal expenses, is about $500,000. This does not embrace the domestic pipe-line supply. The cost of maintenance is about $30,000 per annum. There is a deficit between receipts and expenditures, however. The number of irrigators is about four hundred; acres owned by them, 6,500. The average holding is 16.12 acres; the highest acreage in one holding is 196. The cultivators of citrus trees is 360; number of vine-growers is 260. The average irrigated holding is 15 acres.

SAN DIEGO COUNTY.

The extreme southern division of California is one of the most remarkable of the arid areas within the Union. Along its eastern borders for a hundred miles or more flows the Colorado River, whose turbid waters drain from the heart of the continent. In comparison with all other water-courses it is a mighty flood, the greatest river of the Pacific coast, the Columbia alone excepted, flowing on undisturbed to the sea, past a vast desert which now challenges the power of man to utilize it. Nearly all of California that slopes toward the Colorado, and drains into it, if there be any drainage from a region so seldom and so sparingly visited by rain, is an absolute desert, within whose limits is included nearly three-fourths of the entire area of San Diego County.

The remainder contains the arable portion. A series of mountains separate it from the desert; their axes are generally parallel to the trend of the coast and distant from it 60 to 80 miles. These mountain masses, looked at from sea, do not form a continuous high chain or range, but a succession of peaks and ridges along the upper margin of a sloping plateau. This reaches an altitude of 4,000 to 5,000 feet, and the peaks and spurs maintain an elevation of 6,000 to 6,500 feet, and in one instance, that of San Jacinto Mountain, nearly 12,000 feet.

San Jacinto descends without a break to the edge of the desert basin, whose center is over 300 feet below sea level. Towards the ocean, the slope is gradual and open valleys are met with whenever the contours permit. The coast line is marked by a broad mesh or plain rising from 50 to 200 feet in the first mile, and continuing from 5 to 15 miles until it reaches an altitude of 5,000 feet, where it blends into the ranges. Immediately beyond and generally lower in elevation will be found a series of land locked-valleys drained by separate waterways that cut their courses deeply to the sea. These valleys are becoming the seat of important irrigation enterprises. The mountain landscapes to the east are more attractive and gentle in outlines than those of the Sierra Madre in Los Angeles County or the more ragged aspects of the San Bernardino range. San Jacinto rises to an altitude of 12,000 feet, and by that fact compensates for an extreme aridity produced by the intervention of other mountain ranges to the south and west, which break the course of the rain clouds. The precipitation on San Jacinto, owing to its heavy snows and the lateness of their melting, maintains the flow of streams and springs by which the plains are in a large part supplied.

The streams which drain the western slope of the county seldom flow continuously to the sea during the dry months of summer and fall. The volume of their flow depends, in each case, not so much on the area as on the altitude of their water-sheds. Precipitation over the country is in a marked degree proportional to altitude; least upon the coast, greatest upon the mountain tops. This rule of proportion is very potent in its effect upon irrigation water supply.

The country is naturally divisible into three rain-fall belts, the first of which comprises all the mesas and valleys adjacent to the coast below an elevation of 1,000 feet, and covers an area of about 1,113 square miles. Within this belt are by far the greater portion of lands irrigable that require irrigation, and the greatest area which is generally free from frosts. The rain-fall in this belt is unreliable in character, subject to great fluctuations, the records showing that thirteen years out of twenty-three the rain-fall was less than 10 inches, and during five years was less than 6 inches per annum, while, with one exception, it never exceeded 16 inches. The effect of altitude is made quite plain by the fact that at Poway, 550 feet elevation, the precipitation in 6 years shows an annual average of 17 per cent. greater than on the coast, while at a further elevation of 200 feet more this rain-fall was 42 per cent. greater than at San Diego.

The second belt, an area about 1,400 square miles, has an elevation of from 1,000 to 3,000 feet. The rain-fall is estimated at from 18 to 24 inches. Ex-State Engineer Hall, who is the authority for these statements, puts the rain-fall at from 14 to 20 inches per annum.

The third belt, lying above an altitude of 3,000 feet, has a climate similar to that in some of the Southwestern States, except that summer rains are very rare and light, and the snows of winter not so deep nor long-continued. Its area is about 1,654 square miles, of which, perhaps, three-fourths is less than 4,500 feet in elevation. There are many fertile valleys, heavily-wooded slopes, and a small area of commercial timber within its borders. The rain-fall of this section is often in excess of its tillage duty. It is in this region that the great storage reservoirs must be constructed. The larger streams of the coast all head in it. There are eight of these in the county of San Diego having a total water-shed area of 3,567 square miles. In the first belt the water-shed is 630, in the second 1,282, in the third 1,655 square miles. The higher part of the mountain plateau and northern slopes of its ridges and peaks are wooded with varieties of pine, oak, and madroña. The upper cañons and valleys have sparse growths of oak, laurel, aspen, and madroña. The main ridges and frequently the northern slopes and lesser spurs are covered with dense low growth, commonly known in California as chaparral or chemisal. Along the streams—in the medium range of valleys—there are growths of cottonwood and willow, principally; and along the main streams and on the sandy bottom-lands adjacent to them, similar vegetation abounds, in some places quite densely.

But the entire coast mesa, the broadest parts of the river valleys, the large valleys just within the line of the mesa formation, the greater portion of the plateau region, and a considerable portion of the mountain ridges are treeless and devoid of vegetation, such as is generally thought to conduce to the conservation of waters for the supply of streams. The light rains are all absorbed; and up to a point where the ground becomes well saturated there is but a small flow of surface drainage water finding its way to the rivers; but when this point of saturation is reached, then a large proportion of the waters of precipitation are shed off, and torrents form, which rush to the main drainage lines, and contribute to sudden and excessive freshets in those streams, carrying great loads of sand and finer sediments. The rains ceasing, and there being but a small amount of snow to melt, on a limited mountain area, the streams soon run down.

For reasons given heretofore, there are no large springs or areas of summer drainage of living waters. This, then, is a country where, in the aggregate, an amply sufficient rain-fall may be had to supply an abundance of water, but where, for the most part, it runs uselessly away to the sea. It is pre-eminently a country where the storing of water on a large scale is necessary to maintain any great irrigated area.

The irrigation systems practiced in San Diego County comprise the simplest known, being such as the Indians and Mexicans are accustomed to, as well also the most scientific and thoroughly well organized plans known to irrigation engineering. Several of the largest reservoirs that have been constructed are now in operation. Flume projects have been completed or are under way involving daring irrigation engineering. The reclamation of the irrigable territory of San Diego County, comprising an area of at least 450,000 acres, depends upon the degree of success with which the waters of six streams and the storm supplies above may be conserved by extensive reservoir systems. These rivers are the Tia, Juana, with five small valleys; the Sweetwater, with the same number; the San Diego, the San Diequito, and the San Luis Rey, with three valleys each, and the San Jacinto, with the Hemit Valley. In the first drainage system eight reservoir sites have been selected, with two great conduit flues connected with them. The Otay River projects comprise two large dams and reservoirs, having a capacity of 1,100,000,000 gallons.

The Sweetwater River system is the most extensive of all. Mr. Hall says:

> The engineering works would be notable in any country, and the lesson which the enterprise is working out on the subject of large storage reservoirs for the conservation of winter water for summer irrigation in this dry country is already highly instructive. It is now looked to with satsfaction by San Diegans as a type of what may be accomplished, under even unfavorable circumstances, upon nearly all the streams of this region.

The Sweetwater dam, a short distance above National City, is one of the boldest pieces of engineering in the country. The dam is constructed as a crown arch, and it is the largest of its character in the world.

The San Diego Flume Company proposes a system which, when completed, will consist of a storage reservoir, a diverting masonry dam, and a line of flume 36 miles in length. The method of distribution will probably be by pipes under pressure or by pipe cement channels. The Cuyamaca reservoir, 43 miles northeast of San Diego, covering 1,000 acres and having a full capacity of 499,880,930 cubic feet, is the chief dependence of this system. The diverting dam has a maximum height of 34.5 feet and a length of 447.5; the width of base is 18 feet and the top is 5 feet. The flume has a full length of 36.6 miles. The main pipe line will have a length of 9 miles. A branch pipe will be 1 mile in length and enter the main city reservoir, which has a capacity of 761,000,000 gallons and covers 100 acres. The cost of these works will be a little less than $1,700,000.

The Mission Valley Storage and Delivery Works will embrace eight reservoirs having a total storage capacity of 9,002,000 gallons. The San Diequito system will consist of a reservoir with masonry dam 80 feet high, 400 feet long on the crest, 170 on the bottom, with a capacity of about 3,000,000,000. There will be a second reservoir, with a capacity of 2,000,000,000 gallons, connected by an iron pipe of 30 inches with the upper one. The San Luis Rey flume provides for the construction of a mammoth reservoir dam, a canal from the cañon of the river some miles below, extending about twenty miles along the mountain and rolling hill-sides south and west of the river, and a secondary storage reservoir at the terminus of the canal in Bear Valley at an elevation of 1,300 feet. From this commanding elevation, but 20 miles from the sea at the nearest point, and 35 miles from the city of San Diego, the territory that may be served is only limited by the supply of water available. Pipe lines are projected in various directions. The main conduit drops into this secondary reservoir with a direct fall of seven hundred feet, and the utilization of this water-power and transmission by electricity to points of use are contemplated.

The Temecula Cañon storage reservoir will have control of 800 inches of running water besides its storage capacity. The same will be distributed by means of 10 miles of flume and 2 miles of iron pipe over a considerable irrigable area. The Hemit Valley system is quite extensive; its principal reservoir will be at an elevation of 4,300 feet, 20 miles above the town of San Jacinto, and in a most favorable location. Its largest reservoir surface will be nearly 600 acres and its capacity will then be about 6,000,000,000 gallons. These comprise the modern projects and systems west of the Colorado Desert, in San Diego County. There is a considerable area served by the old style, neighborhood ditches, and by means of wells from which the water is lifted by windmills. In the desert itself, at the eastern base of Mount San Jacinto, a town has been laid out and 6 miles of railroad constructed to connect with the Southern Pacific at the Seven Palms station. The flow of the White Water River is appropriated, and some 200 acres are laid out in orange trees. This is in the desert region proper, and it is probably the forerunner of many similar projects. That any extensive scheme for the reclamation of the desert as a whole will be attempted for many years is hardly probable.

THE STATE ENGINEER'S OFFICIAL DATA.

The following summary was made by Engineer Hall in 1888, and presented to the United States Senate Special Committee on Irrigation in the summer of 1889:

Area irrigated in San Diego County, 1888.

	Acres.
San Diego and San Diequito Rivers	360
San Luis Rey River	480
San Margurita River	312
San Jacinto River	965
Total	2,117

Area irrigated in San Bernardino County, 1888.

	Acres.
Santa Ana River irrigations:	
Santa Cañon:

Stanislaus River	Stanislaus River canals	184
Mokelumne River	Mokelumne River canals	112
Total		251,140

* The area has been increased by at least one-third.

PRODUCTS AND THEIR VALUES.

California is estimated to now have a population of over 1,200,000, of which one-third is found within the semi-tropical and southern portions of the State. Another third or more is found in San Francisco. Ten counties will contain over one-half the population.

The immigration increase in 1889 was 30,557.

In 1889 the California wheat product was 42,000,000 bushels.

Value of wheat	$32,000,000
That of fruit	16,000,000
Barley	9,000,000
Cereals unspecified	7,500,000
Wine and brandy	8,000,000
	72,500,000
Out of a total of raw products that include gold, silver, coal, etc	144,704,000
This leaves a balance of	72,204,000

The entire agricultural products of California since 1848 have been as follows:

Wheat	$732,000,000
Dairy	200,500,000
Barley	184,000,000
Wood	161,000,000
Fruit	106,000,000
	1,383,500,000

California—1888-'89.

	Acres.
Area of oranges	50,195
Area of lemons	3,015
Area of raisin grapes	20,000

It is in the great diversity of altitude and precipitation that the irrigation needs of California and the means of supplying them are found. Storage in the mountains and good engineering in the way of distribution will add enormously to the irrigable area of this wonderful State. Every system of water usage and distribution can be found therein; its practices illustrate the primitive wastefulness common to early irrigation, and the remarkable economy in the use of water which intensive farming and horticulture have already produced in the extreme southern portions of the State. Nowhere else in the world, except Madeira, portions of China, and Central Asia, has the "duty of water" been so thoroughly extended. As a consequence the price of land, the cost of water, and the security of crops have all grown in a steadily increasing ratio. Within twenty years land which the owner protested against being taxed at 75 cents per acre has been sold and is now selling at from $500 to $1,500 per acre. On the tract referred to more people are supported per acre and in greater comfort than elsewhere in the world.

The areas of fruit-producing lands on which this occurs are small in extent at present, though they are quite numerous. These areas may be greatly increased by proper systems of water storage. They may be largely added to by the restoration and conservation of the underground supplies so steadily fed by the neighboring mountain drainage.

It is difficult to make anything like a close approximation of the reclaimable area of California. With the water "in sight" certainly 12,000,000 acres will be a low estimate. Water storage on a grand scale, such as the conditions warrant, will insure the reclamation of at least 20,000,000 acres. A large proportion of whatever area may be reclaimed will necessarily be devoted to the raising of products possessing a high market value. Its fruits are among the best in the world. It bids fair to become the successful rival of the oldest wine-growing and wine-making lands; its nectarine, prune, grape, and orange are already found in the markets of the world. The olive, fig, lemon, date, and other semi-tropical fruits are fast becoming of great commercial importance. Nearly all these products are the direct results of irrigation, and they are all benefited by its judicious use. There were 1,537,000 fruit-trees reported in the State at the beginning of 1890.

The enormous addition to the wealth of the State and to the commercial prosperity of the whole country, which is the direct result of the high culture produced by irrigation, warrants a close attention to the united appeal of the people of California for such a survey of the public lands remaining therein and of the State's capacity for water storage as will insure to them that accurate knowledge which enterprise and investment require in the conduct of great affairs.

TAXABLE VALUES OF CALIFORNIA, 1879-1889.

A careful tabulation of the assessment valuations in some of the counties of the State illustrates very forcibly the great increase of wealth produced by the practice of irrigation. It must be borne in mind that the figures given are not over 50 per cent. of the real values.

GROUP NO. I.—*Counties enriched by irrigation.*

[Total taxable values.]

Counties.	1879.	1889.	Increase 1889.
Fresno	$6,354,596	$35,387,173	$29,032,787
Kern	6,005,460	11,831,780	5,826,320
Los Angeles	16,368,649	84,376,319	68,007,670
Merced	5,208,245	14,146,845	8,838,600
Orange	2,317,700	9,270,767	6,953,067
San Bernardino	2,576,072	23,267,955	20,690,982
San Diego	3,525,253	31,560,918	28,034,265
San Joaquin	17,377,129	38,802,606	21,425,477
Stanislaus	6,232,367	15,594,003	9,361,636
Sacramento	18,416,338	34,464,174	16,047,836
Solano	2,651,367	6,966,007	4,314,640
Tulare	5,204,777	24,343,013	19,138,236
Yolo	10,177,427	20,911,325	10,733,898
Total	102,516,281	350,922,885	248,405,414

Orange County was not formed in 1879. It was then part of Los Angeles County. The ratio estimated for increase is on one part in 1879 to four parts in 1889.

GROUP NO. II.—*Counties increasing in irrigation activity.*

[Total taxable values.]

Counties.	1879.	1889.	Increase 1889.
Butte	$10,743,426	$20,730,252	$9,986,826
Colusa	12,420,508	24,365,995	11,945,487
Lassen	1,230,764	2,527,449	1,306,685
Inyo	1,353,300	1,548,695	185,395
San Benito	3,947,728	6,332,911	2,385,183
Shasta	1,961,436	6,594,003	4,632,567
Siskiyou	2,651,367	6,966,007	4,344,640
Sutter	4,120,451	19,079,868	5,959,417
Tehama	4,199,998	11,901,255	7,701,257
Trinity	868,496	1,153,344	284,848
Yuba	4,293,630	7,046,316	2,752,686
Total	47,791,104	99,246,095	51,544,991

GROUP NO. III.—*Foot-hill counties partially irrigated.*

[Total taxable values.]

Counties.	1879.	1889.	Increase 1889.
Amador	$2,468,642	$4,281,969	$1,813,327
Calaveras	1,871,850	4,315,461	2,443,611
El Dorado	2,312,590	3,879,887	1,567,297
Mariposa	1,295,048	1,849,641	554,593
Nevada	6,305,090	6,926,218	621,128
Placer	5,774,860	10,118,060	4,343,200
Plumas	2,115,173	2,309,441	194,268
Tuolumne	1,596,015	2,716,465	1,120,450
Total	23,739,268	36,397,142	12,657,874

The bay counties of San Francisco, Alameda, Contra Costa, Marin, San Mateo, Sonoma, and Napa present the following comparisons:

Valuation in 1879, a total of	$333,146,966
Valuation in 1889, a total of	449,992,603
Making an increase of	116,841,637

These counties are partly affected by irrigation, to the direct extent at least of one-tenth part of the valuation given.

The remaining fourteen counties, of which nine are coast counties, show the following results:

Valuation in 1879	$70,755,631
Valuation in 1889	156,039,572
Increase in ten years	85,283,941

Thus it will be seen that from 1879 to 1889 the taxable valuation increased from $577,949,250 to $1,092,598,297, an addition of $514,649,047. Of this increase nearly one-half, or $248,405,414, was made in thirteen counties, or one-fourth of the State, and is almost wholly due to irrigation. It may be fairly estimated that to the increase of irrigation in California and the rise in land values, etc., as a consequence, is due at least $350,000,000 of the total taxable increase in valuation. That will be a marketable increase of $700,000,000.

THE IRRIGATED AREAS OF CALIFORNIA.

California, though foremost in the extent and variety of its irrigation interests, enterprises, and methods, is behind several other communities within the arid region as to its statistics and data.

A full, clear, succinct statement of the irrigated areas, number of ditch systems, and the mileage, with the cost thereof, is not accessible. The best average estimate obtainable, consulting therefor the State engineer's reports, the State board of trade, evidence offered by local witnesses, and county assessors' returns to the State board of equalization, is the following:

	Ditches.	Cost per mile.	Total cost.
	Miles.		
In the San Joaquin Valley, counties of Fresno, Merced, Kern, and Tulare	800	$5,400	$4,320,000
In the counties of Los Angeles, Orange, and San Bernardino	500	6,000	3,000,000
In San Diego County	36	19,613	700,068
In the remaining part of the State, twenty-four counties, where irrigation is practiced	1,700	640	1,128,000
Counting one-third of the mining ditches in the State as available, and used for small irrigation, we have	289	3,188	921,221
Total	3,825	....	10,375,289

The total valuation or cost given is below the true figures. Much of the data on which the estimates are based is taken from the assessors' returns made for the purpose of taxation. They can therefore be doubled. That will give a total cost of at least $20,000,000.

The acreage is also difficult to arrive at with certainty, but it is fairly covered as follows:

	Acres.
In the San Joaquin counties:	
In farm crops	1,000,000
In vines	13,000
In fruit trees	16,000
	1,029,000
In the southern counties:	
In farm crops	580,000
In vines	45,000
In fruit trees	85,000
	710,000
In the balance of State (irrigated):	
In farm crops	1,500,000
In vines	25,000
In fruit trees	30,000
	1,555,000

The total acreage wholly under ditch and now irrigated is fairly within the annexed totals:

	Acres.
In farm crops	3,080,000
In vines	83,000
In fruit trees	131,000
Total	3,294,000

If all the areas directly cultivated by the aid of natural sub-irrigation, etc., be added, the total area in California will certainly be not less than 3,500,000 acres. The point of interest, however, in these figures is the profitable character of such cultivation, especially in the matter of fruit-raising. Land formerly worth $1 now sells at from $500 to $2,500 per acre. The area of California is reported by the statistician of the Department of Agriculture to be divisible as follows: Tillable, 39.8 per cent.; grassland, 11.5; woodland, 35.5; unproductive (valuable, though, because largely mineral in character), 11.4. These areas compare favorably with the whole country, the per cents for the same divisions of which are as follows: 41.6; 11.5; 35.4; 11.4. In productive character California shows on grain the following:

[Bushels per acre.]

	For State.	For United States.
Corn	26.5	24.2
Wheat	13.0	12.3
Oats	28.2	27.0

THE INTRA-MOUNTAIN DIVISION.

Within the limits of the second great division of the arid region extending east and west from the one hundred and fifth to the one hundred and twentieth degree of west longitude, and north and south from the British to the Mexican boundary, irrigation works and experiments of value will be found in progress, small in extent, perhaps, in most cases, but extensive when aggregated.

The larger portion of Colorado, New Mexico, and Wyoming are within the limits assigned. The whole of Nevada, Utah, Montana, Idaho, and Arizona, and the eastern half of Oregon and Washington Territory are also included. The region comprises 15 degrees of longitude and about 17 of latitude, and makes a total area of 1,100 by 900 miles square.

IRRIGATION AND STORAGE IN IDAHO.

The condition of Idaho, as to the hydrographic facts, the available area for reclamation, the facilities for artificial storage, and the awakened interest of the people, was found to be among the most satisfactory of the communities visited by your committee. A considerable area to the north and to the west of the Sawtooth and Bitter Root ranges is considered in the Territory as outside of the arid range. This area embraces the counties of Idaho, Latah, Nez Perces, Kootenai, and Shoshone. A portion of Lemhi is also included. Unquestionably, however, this section will also be benefited and farming pursuits rendered more secure by water storage and distribution. The remainder of the Territory embraces 32,183,040 acres, of which about 7,000,000 acres are estimated to be irrigable and arable, fertile in soil, and having accessible storage capacity and an available water supply.

The counties wherein are found the largest irrigated areas, as well as the great number of ditches with the smallest service to each, are those in which so large a number of Mormon citizens have settled. The smallness of the ditches constructed indicate the limited area cultivated by each individual or family. It is, however, always sufficient to support them in that primitive plenty which constitutes their standard of life. The primary nature of this work can be seen when an estimate is made of the cost per acre.

In Bear Lake County the total cost for the 21,500 acres irrigated is given at $73,500, or a fraction over $3.60 per acre. The ditches of the northern portion of Bingham County cost $435,000, or a cost per acre of $1.775. Small as this price appears to be, it is necessarily costly, because wasteful. As the water in sight is absorbed, storage becomes a necessity, and the result is the abandonment finally of the small ditches, and the reconstruction of service works on a larger, and of necessity, costlier (at the outset) scale. Taking the medium between the two rates given, and the cost per acre of irrigation in Idaho may be set at $2.66 per acre, or a total for 715,500 acres of $1,187,000.

The extensive river system of Idaho renders the reclamation of its arid lands a very interesting problem. The need of storage is insisted upon. The importance of the river system of Idaho can hardly be exaggerated from the stand-point of reclamation; the number and volume of minor mountain streams must also be considered. Some slight idea of the water supply may be obtained by the presentation of a few of the estimates made in the testimony:

	Cubic feet per second.
Flow of Snake River (at Eagle Rock)	5,000
Flow of Salmon River (in Cassia County)	1,820
Flow of Boisé River	6,000
Flow of Payette River	1,000
Flow of Weiser River	180
Flow of Big Wood River	154
Flow of Raft River	745

These estimates are necessarily partial. They embrace with tolerable accuracy the surface drainage flow above the point of measurement, but they take no account, of course, of the addition to the river volume accruing from the remainder of its other local areas of precipitation and drainage. The average annual rain-fall is about 13 inches. The snowfall is given at an average of 6 cubic feet of packed snow on the ranges. This will give at least, in melting, about 2 cubic feet of water. The capacity, then, of Idaho for storage by main reservoirs at high altitude and at or near the sources of its great streams becomes one of the problems that may be approximately measured and calculated upon.

The Hon. E. A. Stevenson, of Boisé City, Idaho, presented to the Senate Committee on Irrigation, at their Idaho session, valuable testimony as to the value, character, and results of irrigation. A brief summary of its chief points is given. Mr. Stevenson said:

> This town was settled in 1863, but very little agriculture was attempted until 1864 or 1865. When I first saw this town this portion around here was as poor a sage-brush place as you would find in Idaho—a miserable sandy place that nobody imagined would grow anything. It was that way all along this valley. There was a little strip along the river where some grass grew and where there were some willows and trees. The first men who came here settled on that low bench-land, and they have the poorest farms in the country. Those who went back on the sage-brush plains have land that is worth five times as much as the other. And so it is in Washington Territory, at Walla Walla. All those men who went on the Touchet, and all those streams, have poor farms; those who went on the high lands have good farms. But this land without irrigation would produce nothing. It might, if it should rain in the fall, produce a crop of rye, but there is no dependence to be placed on it. But rye will grow almost any place. I have had some experience with irrigation. My partner and I dug a ditch 22 miles long down on the Payette River. We took some water on to some desert land that we have there, and in five years we have raised orchards with lots of fruit. I have cut the grass there twice this year already, and there is a regular forest where there was not a tree in sight in the country. In a short time, five years, these trees were 5 inches through.
>
> The trees are apple, pear, plumb, peach, apricot, prune, and poplar trees; box-elder, walnut, locust, and all the different varieties. I took small trees in a two-horse wagon down there. I told some persons that five years ago I took in a two-horse wagon all the trees that are growing there to-day, and they were thunder-struck. A man can not imagine that it could be done. But it is marvelous how the trees grow there. I do not think you can raise cereals where you have to irrigate and compete with a country that does not. But in all other kinds of crops, vegetables, I think we can raise all kinds of fruits and vegetables. An irrigated country requires more population. The holdings should be small. A small farm will support a good family if it is well irrigated. The system of irrigation is crude. They do not understand it. Some give too much water and some too little. Some farmers might live on 60 acres. But I think it would be better for the country to cut it up into 80 acres; 40 acres would make a good home if well cultivated. Now, on the Payette River the supply of water is abundant without storage, and will water all the land on it. There is a large amount of water there now. But on the Boisé River it would need storage. There is plenty of water here with proper storage facilities to cover the whole country. I am speaking of Lewiston. Around the city of Lewiston they could not raise fruit in the garden without irrigation. They irrigate there altogether.

L. F. Cartee, formerly surveyor-general of Idaho, and a practical horticulturist by irrigation, gave to the Senate committee the results of his own work and observations. He said in substance that—

> Idaho sage-brush land is capable of producing anything that can be raised in this latitude anywhere, not only all the varieties of fruits, but all the cereals. I have forty different varieties of grapes on my place, and they nearly all ripen except the Catawba. That does not ripen because of the shortness of the season. Our grape is of fair quality; better than any of the eastern grapes that we have. A fair crop of wheat on our irrigated land is from 25 to 50 bushels; of oats it is from 30 to 60 bushels; occasionally 70 to 80 bushels, but that is exceptional; barley is the same as wheat—25 to 50 bushels. Timothy hay averages about 2 tons to the acre, and alfalfa returns 6 tons. Red clover will give the same. Potatoes return 600 bushels to the acre. This is the finest apple country in the world. All do well here; you

can hardly find an exception. They grow to a large size and the trees are heavily loaded. Peaches do well, but plumbs and prunes do remarkably well, better than in any country in which I have been. Pears are very good also.

At the same session fruit, still on the branches, was exhibited. One limb, 2 feet in length, had on it 29 peaches, one of which taken off at random measured 8¼ inches one way and 8¾ another. On a branch 14 inches in length 27 large plums were counted. A pear was measured and found to be 11½ and 10½ inches in circumference. These are reported as taken without selection from a large variety.

MONTANA AND WATER STORAGE.

Montana, with its 93,349,200 acres, is not only one of the three largest States—the others being Texas and California—but it is without question the best watered one west of the one hundredth meridian. It is heavily timbered also; its pastoral area is great, and, according to the estimate of Statistician Dodge, its tillable area is not less than 32.9 per cent., or close to one-third of the total.

The river courses that drain the central basin of our land find their beginnings in the sources of the Upper Missouri, with its great tributaries of the Yellowstone, Gallatin, Jefferson, Madison, and a score more important streams that all head in and receive their primal supply from the precipitation and drainage of the upper Rocky Mountain ranges. The valleys are usually narrow and long. The Yellowstone is an example, presenting as it does a tillable valley or bottom area of about 400 miles in length, with an average width of not to exceed 3 miles; in all about 780,000 acres. Such streams, large or small, usually present similar features of deep, narrow valleys, in which the waters appear to be slowly but steadily eroding deeper channels; then comes a precipitous rise to the mesa or bench land of from 25 to 100 or more feet in height. The mesas will widen their sections of the several hydrographic basins to from 8 to 12 miles in width. The secondary table-land or plateau is then reached by steep ascent, making them often as high as from 600 to 1,000 feet above the bottom-land. These mesas and table-lands are everywhere covered with succulent grasses. They are everywhere found to be fertile in capacity, if water can be obtained. It is these facts that make Montana a typical region in which to conserve the waters by storage and subsequent distribution for purposes of irrigation.

The Yellowstone Basin, from a reclaimable area in the lower valley of 780,000 acres, will rise rapidly under a system of scientific engineering to an agricultural capacity of from 3,000,000 to 8,000,000 acres. When storage shall be so advanced and distribution so systematized that the secondary table-lands may be reached and quickened, the largest area named will be readily compassed. Nor does this statement close the possibilities of the drainage or hydrographic basin of the Yellowstone. The tributary valleys found there, many of which are quite large, will furnish an additional 4,000,000 acres to the area of reclamation. This is illustrated in a report made by the authorities of Custer County, within which a large portion of the main Yellowstone Valley is located. That report gives the valley land area at 384,000 acres, and for fifteen other tributary valleys within the county, including the Tongue, Powder, Rosebud, and Otter, it gives their valley areas at 501,600 more acres.

The volume of water to be supplied from the Yellowstone alone is estimated by the same authority for use in the areas under consideration at 906,000 miner's inches per second, flowing under a 6-foot pressure. The testimony warrants the statement that the Yellowstone alone can furnish for irrigation purposes some 4,000,000 miner's inches. With proper storage this may be greatly increased, perhaps doubled. The wisdom of the policy which reserved as a national park the wonderland in which the Yellowstone finds its ample sources may yet be proven in ways heretofore unexpected. The storage of its quickening waters will be greatly simplified by the inability of speculative occupiers of the public lands to exploit those valuable sources. Hundreds of millions of dollars may yet be added to the nation's wealth as a consequence of the National Park reservation.

The Yellowstone is taken as an illustration of the fact that the earlier or primal attempts at irrigation are decidedly wasteful and often provocative of contention, disorder, and litigation. The valley or bottom lands, though the most readily reclaimable by simple local ditches, are seldom, perhaps never, the most desirable for farming purposes. It is always the warm red loams and soils of the mesa and table lands that will furnish the largest crops as a return for industry. It is on these benches, open to the sun, made up of the most fertilizing components and readily washed by water of alkali salts, that the Western farmer will in the not distant future, wherever water is accessible, make from his occupation a return almost as certain and controllable as does to-day the carder of wool and the weaver of cloth.

No cultivation of the soil is possible in Montana without irrigation. Without ample storage of water the reclaimable area will be a limited one; with ample storage it will rise, according to different witnesses and reports, from 20,000,000 to 30,000,000 acres. With irrigation an acre of ground in Montana will exceed in productive value from 3 to 5 acres in the humid or rain-fall States. The average production per acre is estimated as follows: Wheat, 35 bushels; oats, 50; barley, 45; corn, 28; alfalfa, from 4 to 6 tons. The percentage of productive capacity for Montana per acre may be stated as follows:

	Products.		
	Wheat.	Oats.	Corn.
Average number of bushels per acre in Montana	17.8	34.2	26.2
Average for the United States	12.3	22.3	27.0
Average per acre for whole arid region	18.9	24.9	28.9

The number of farms is 1,519, the percentage of agriculturists 20, and the average value of land is a little less than $8 per acre. During the past ten fiscal years 6,904,461 acres of public lands have been disposed of in Montana, of which total 5,304,778 acres have been settled upon, sold, or patented during the past four fiscal years ending June 30, 1889.

The statistics presented as to irrigation ditches were very imperfect. It appears that there were in 1869 of mining ditches 287½ miles, constructed at a cost of $806,500. The present extent, including these, as many have been used for irrigation purposes also, is now estimated at 1,000 miles. There are now partially or wholly completed the following larger or district systems, constructed for rental investment by corporations:

Ditches.	Miles.	Acres to be served.	Estimated cost.
Benton Lake	35	50,000	$175,000
Clarke Fork	38	100,000	140,000
Chestnut Valley	10	25,000	7,000
Dearborn	45	51,000	150,000
Florence	50	10,000	200,000
Gallatin	25	50,000	75,000
Sun River	75	300,000	500,000
Teton	40	35,000	80,000
Total	318	611,000	1,327,000

Under a proper system of irrigation, storage, and distribution land now worth but little beyond the Government price of $1.25 will rise rapidly to $20 and $30 per acre.

EASTERN WASHINGTON AND OREGON.

The States of Washington and Oregon present interesting irrigation and reclamation features. In an area well within the arid region, the extensive mountain lakes found in northwestern Montana, northeastern Washington, and northern Idaho subdue to a considerable degree the regional aridity. The extreme eastern quarter or third of Washington from north to south may properly be classified as subhumid, while the central portion clear to the eastern foot-hills of the Cascades approaches more nearly to a general arid character. Washington, from 117° to 121° of west longitude, or four degrees, will be found a section in which the storage and distribution of water, while not at all times and places therein an absolute necessity, will always need such facilities and find them to greatly enhance its land values and industrial progress. There is a great area almost wholly unreclaimed, formed by the mesa or table-land of the Columbia River Valley and its great tributaries. The Columbia River Plains to the northwest of the North Pacific Railroad will probably require for their arable use an extended series of hydrographic works. That they can be so reclaimed is testified to from many sources. One estimate is made of 8,000,000 acres, another of 12,000,000. Irrigation by private parties or companies has been successfully tried in a number of valleys, viz: The Klamath River Valley, both in Oregon and northern California; the Boisé River Valley, Idaho; the Snake River Valley, Washington and Idaho; the Colville River Valley, Washington, and in the Rogue River Valley, Oregon. The rivers of this region are large and furnish enough water to supply systems of irrigation ditches, which could be supplemented by storage reservoirs if necessary, or when the demands increase. The region around Walla Walla is rich and productive. The Great Plains ot the Columbia, although not so well known, is a promising country. Both regions are poorly supplied with water during the summer months, at least. The Snake River above Lewiston has falls and rapids, and may afford an opportunity of running irrigation ditches to the lower lands below.

All of the great bodies of water named present the usual characteristics of the arid region—deeply eroded channels, low, narrow valleys, abruptly rising bench lands opening widely one or the other side of the river, but seldom on both sides, and then again rising into grass-clad table or plateau lands. At North Yakima and Ellensburgh can be seen the results of irrigation on an extensive scale. The Moxie ranch at the first-named place illustrates in its 7,000 acres, irrigated from the Yakima River at an average cost of $8 per acre, what may be accomplished by private enterprise backed by capital, while at Ellensburgh the Kittitas Valley offers a splendid evidence of neighborhood energy and self-dependence. The Yakima Valley people estimate 200,000 acres of bottom lands for reclamation and at least a million more in available bench lands. The rain-fall of the region is also sufficient to secure a large area of "subirrigated" land. That is to say, where the soil retains below the surface much of the precipitation and drainage that percolates into it.

The production per acre is given of wheat at from 35 to 50 bushels; of oats at 60; of barley from 50 to 80; alfalfa yields from 6 to 10 tons per year, while potatoes will return more than 500 bushels to the acre. One half of eastern Washington needs storage and full facilities of irrigation. The cost will range from $3 to $5 per acre, and there may probably be found an abundance of water for storage. The cost of water in irrigation is about $1.50 per acre.

The Kittitas Valley without water is but a sage-brush desert; irrigated, it becomes a garden spot and produces bountifully of cereals, fruits, and vegetables. About 22,000 acres of land are now under cultivation. All small fruits, as well as apples, plums, pears, etc., grow to perfection; peaches do not do so well, except in localities bordering on the Columbia and Wenatchee Rivers. Vegetables of all kinds and of the finest quality are grown upon every farm.

In these valleys of the Yakima, including the Nachez Valley and the Yakima Valley proper and the valleys tributary to the Yakima, the irrigating season commences in the months of May and June principally. Very little land west of the Columbia River, in what is known as the Columbia River basin, is susceptible of cultivation without irrigation except, perhaps, for hay. Many people produce hay along the river by subirrigation or percolation. The finest store-house of water is the snow-clad mountains. Fort Adams is an everlasting store-house. The waters of the Yakima and the Tietan flow in there in ordinary seasons, and without any storage whatever those would irrigate an extremely large area of country.

In the extreme southeastern section, around Pasco, Walla Walla, and east to Lewiston, in Idaho, there is a region famous for fine fruits and vegetables, in which the use of irrigation adds enormously to the value of the land. It is a region also of accessible and not very deep artesian water, and it illustrates, too, the rapid increase of precipitation at rising altitudes. The average annual rain-fall at Walla Walla is given for five years past at 18 inches; at Dayton, 30 miles distant, it reaches 27 inches. That is a rise of less than 700 feet. To be accurate, the height above sea-level at Walla Walla is stated at 1,000 feet; at Dayton, at 1,675 feet. The advantages offered by this region are testified to by some State census figures, which show that the proportion of settlement in Washington during two years past has been in favor of the section east of the Cascade range. In 1887 there were in Washington 144,000 persons; in 1889 the estimate made from county returns showed 240,000. In the western counties the total population was 142,132; in the eastern counties it was 97,868; an excess for the west of 44,264. The total increase for two years is given as 95,991. Of this, the region between 117 degrees and 121 degrees, or East Washington, got 41,298, while that west of the Cascades got 35,693.

Oregon is estimated to have received 100,000 new settlers during the same two years or less, of whom 60,000 at least have remained east of the one hundred and twenty-first degree of west longitude. During the past twelve fiscal years ending June 30, 1889, these two States show a public land settlement as follows: Washington, 13,335,937.03, and Oregon, 6,149,540.05 acres, or a total of 19,485,477.08 acres. The amount paid into the land offices during the fiscal year of 1888–'89 was, for Oregon, $35,332; and for Washington, $39,538, or $74,870; or a total of one-eighth of the receipts for the whole arid region. Washington has made natural waters public property by constitutional provision.

The arid and subarid sections of Oregon are somewhat more extensive than the similar ones in Washington. Their great feature is the drainage basin of the Columbia River, in the north, with its extensive tributaries—the Deschutes, John Day, White, and Powder Rivers—and on the east the lower valley of the Snake River, which forms the western boundary line of Idaho for two-thirds of its length. Below that is the Oregon portion of the Owyhee River and its branches. In the southwest, the Klamath River and lakes form an extended drainage basin, in which large irrigation operations have already commenced.

IMPORTANCE OF IRRIGATION IN UTAH.

Utah presents an extensive system well under way. A large area has been reclaimed. The value of the work accomplished is seen not only in the valleys near to Salt Lake City, but in all the Mormon settlements within the Territory. The influence of the Mormon polity in directing industrial activity has often been commented upon. In no one thing is it more apparent than in this great work of the conservation and distribution of the water supply. It exhibits several noteworthy features. They are:

(*a*) The treatment of natural water supplies, under legislation, as public property, to be used for the common benefit.

(*b*) The construction of all distributive agencies (artificial) at the cost necessarily of those to be benefited.

(*c*) The incorporation of the expected beneficiaries by neighborhood companies, under general law, and the assessing of costs co-operatively, by means of share purchasing and holding, according to the number of acres to be served by the water so utilized.

(*d*) The distribution of water under stated regulations, which have the effect of law, under the supervision of an officer specially chosen for the purpose.

(*e*) The payment for this authorized use by means of stated rates, levied upon the volume of water used.

The Mormon irrigation laws provide for the proclamation as a water district of any piece of territory which can be commanded by an irrigating ditch, the nomination of water masters, penalties against wasting water, the giving of permission to carry the ditch through any private property upon a fair valuation for the land used, authority to tax for maintenance of channels, and to appoint taxation trustees, whose powers are made very broad with respect to determining what shall be described as land benefited by the construction of the irrigating channels. The law also gives protection to primary water rights, which means that any person who has drawn water from a water-course by means of an irrigating work previous to the proclamation of any locality as a water district, has his right protected as a primary claim up to the quantity of water he was in the actual use of at the date of proclamation. Having covered these points the law has made the way open for the action of private enterprise, which in all cases undertakes the construction. The next step is the formation of a joint-stock company, which may be formed of not less than three individuals, and not more than seven, and further provides that such corporation work shall be exempted from general tax for county and State purposes, to which all other kinds of property are subject. The farmers and others interested then meet in public and arrange the formation of the company and the distribution of shares, and then vote as to whether the tax for maintenance and management purposes, after the main ditch has been completed, shall be upon all the land within the water district or upon "the land to be benefited." They can also confer arbitrary powers upon the assessing trustees, as a difficulty had been found to occur with parties who refused to contribute to the maintenance tax on the plea that they are not taking water, although, owing to favorable positions in relation to either the main or subsidiary ditches, their lands are being effectually irrigated by means of seepage. The shares are always $10 each, and each share represents an acre of land with a perpetual water right to that acre, subject only to the maintenance tax. The company being formed, the farmers, or intending farmers in most cases—for many of the tillers have just arrived as immigrants—of the water districts take up all the shares they can. This is usually a very small percentage of the whole, as they are poor, and their shares are mainly paid for by work in the ditch. After the farmers have taken their shares, the wealthy citizens take the balance amongst themselves, and on goes the making of the ditch, the intending farmers working on their farms at the rate of $20 a month, and the non-working shareholders putting on labor by contract, which amounts to an average of 10 cents per cubic yard, the heavier work in the cañon being by special agreement, according to the difficulties of the work. When the work is completed the farmers have as many water rights as they have taken out shares, and they who have furnished most of the capital then begin to make their profit.

Small farmers generally secure a water right for each acre, but others who hold, say, from 40 to 80 acres, sometimes only take water right sufficient for half their area, working one-half as a tillage-farm and the other as a grazing-block, alternately. A water right means the privilege of taking as much water as the land requires during the irrigating season, and the maintenance tax varies from 10 cents to 16 cents per acre per annum, according to "easiness" or otherwise of the channels. Subsidiary ditches, called laterals, are made by the farmers at their own cost, from side heads fitted with sluices, through which the water-master lets out as much water as may be required during any particular day. Thus there may be ten farmers along a certain lateral holding from 5 to 40 acres of land each, and they may have water rights to cover the whole or any part of their holdings. The water-master knows how many water rights are along each lateral, and every morning he looks at his notice boxes, which are attached to the sluice-heads at the place where the laterals leave the main channel. The farmers generally arrange to irrigate day about, each at the proper time posting up the notice, "I intend to irrigate to-day," and as the water-master knows how many acres are possessed by the person signing, and how many water rights, he is able to make his arrangements accordingly. His water-gauge, which is simply a wooden slat in the lateral sluice-head, graduated so as to let a certain number of cubic feet run through in a given time, is then lifted to the necessary mark, and the water laid on until the irrigation is completed. The gauge is arranged so as to let a cubic foot per second flow through for each hundred acres of land. Thus: If A's notice represents five water rights, B's fifteen, and C's thirty, the water-master knows that fifty water rights want water, and he sets the gauge to run at the rate of half a cubic foot per second. This is not for the purpose of measuring the water, but only as a gauge to arrange the flow to suit the irrigation requirements of the several farmers situated along the lateral.

The time occupied in flooding a certain area differs according to the "lay" and quality of the soil. The water-master soon learns how much time each irrigator usually occupies, and his knowledge on that point, together with the law against wasting water, which is strict, operates to prevent the flow of water longer than is absolutely required. The water-master notes in his book the time of letting the water on, together with the number of water rights that are drawing, and it is his business to visit the irrigators about the proper time, and see about shutting off.

THE WATER LAWS AND PRACTICES.

The legal aspects of Utah irrigation are thus as remarkable as the economic ones. Indeed, they are related to each other, and the laws could hardly have been framed by any other community. But their value extends beyond the locality for which they were framed. Prior appropriation is the foundation, but so modified by the uses of water in the interests of the community as to make of that principle something quite broader and more equitable than has elsewhere been the case. In other words, priority has not been abused in Utah. The county selectmen are *ex officio* water commissioners, with the power to record all appropriation and regulate the distribution of natural water. Appropriators can be persons or corporations. Rights are divided into primary and secondary, the latter being a feature of water legislation peculiar to Utah. A primary right vests under the following circumstances:

(1) Whenever any person or persons shall have taken, diverted, and used any of the unappropriated water of any natural stream, watercourse, lake, or spring, or other natural source of supply.

(2) Whenever any person or persons shall have had the open, peaceable, uninterrupted, and continuous use of water for a period of seven years.

A secondary right to the use of water for any of said purposes is hereby recognized and acknowledged to have vested and accrued (subject to the perfect and complete use of all preliminary rights) to the extent of and reasonable necessity for such use thereof, under any of the following circumstances:

(1) Whenever the whole of the waters of any natural stream, watercourse, lake, spring, or other natural source of supply has been taken, diverted, and used by prior appropriators for a part, or parts, of each year only; and other persons have subsequently appropriated any part, or the whole, of such water during any other part of such year, such person shall be deemed to have acquired a secondary right.

(2) Whenever, at the time of an unusual increase of water exceeding seven years' average flow of such water, at the same season of each year, all the water of such average flow then being used by prior appropriators, and other persons appropriate and use such increase of water, such persons shall be deemed to have acquired a secondary right.

The measurement of water is definitely provided for by "fractional parts of the whole source of supply" or time limit, or by a specific ratio of measurement, or this combined with time limit. Provisions are made for repairs, damages, continuous use and service, against waste, and for the return of unused water to its proper channel; also for pro rata distribution when supply fails in volume, as to equal right of way, and for the organization of local copartnerships or corporate direction. Another act provides for irrigation districts and their lawful control, with trustees, and the powers as to water and its control and use, of any subcivic or county body.

There are two or three systems of distribution. First are the incorporators on the streams, controling it themselves—they agree how it shall be manipulated; second, the county courts that matured and organized irrigating companies; and, third, private corporations, taking out charters the same as any other corporation would, as, for instance, a person or a company of men settle upon a stream and appropriate the water in it. In early times they had sufficient to irrigate what land they would break up. These may be termed the primary owners of the water. Afterward others, finding a surplus of water in the stream, appropriated still further water, and so on until all the water of that stream is taken out. In establishing some streams there is then what is known as the first, second, and third right. The third right, when there is a scarcity of water, shuts off the entire stream, and the second and first rights take the entire stream. The owners of each of those ditches meet and appoint what is called a "water-divider" or "water-master," who has control of the ditch for that year, and whose duty it is to divide the water of the streams into ditches. For instance, if there were four streams drawing water, the farmers would appoint a divider to turn the water of those streams into the ditches, and the water-master take the water as it flows into the ditch and give it to the owners as their rights appear. The private companies so called are incorporations where certificates of stock are issued under the general laws of the Territory. They elect their board of trustees and manage the affairs of the company. Those trustees appoint a water-master, who takes the number of shares each owner of has and divides to each his proportion of the water that comes through a certain ditch from the stream. Those streams are mostly artificial streams, having been taken out from some large body of water. That system prevails largely on the west side of Salt Lake. The stockholders have the land, but the water right can be transferred without transferring the land. It is a water right independently of the land.

Yet the water must be "in place," and in order to use it, the land served by that way must be obtained. As a practical fact a water right, that is, one share in a corporation, represents only the service of water for 1 acre of land. And it is a particular acre in a special place. Therefore the one share of water can only serve that 1 acre of land, or rather any 1 acre within the area to be irrigated by that particular body of water in the service or duty of which one share has been obtained.

In the distribution of water the horary or time system has been adopted. The irrigation survey engineer states that the following forms indicate the method of distribution by "the hour," as is the case in Spain:

No. —.

TIMPANOGOS IRRIGATION TIME TICKET.

Mr. ——— ———. On ——— every alternate week, from — o'clock — m., and until — o'clock — m., ———— amount of stream, all of the water in said ditch.

——— ———,
Water-master.

No. —.

TIMPANOGOS IRRIGATION TIME TICKET.

Mr. ——— ———: You are entitled to the use of water from the Timpanogos Ditch on ——— every alternate week, from —— o'clock — m., and until —— o'clock — m., ———; amount of stream, all of the water in said ditch; when you are required to discontinue to use and turn it off.

——— ———, *Water-master.*
Per ——— ———, *Deputy.*

PROVO CITY, UTAH, ——— ——, 18—.

The annexed blank receipt shows the manner of meeting the water-tax levy on proof of labor performed.

No. ——
Am't of labor, ——
Am't of cash, $——
——
Total, $——
Issued to and received by
—— ——.
Date, ——, 1.8—.

No. ——
Received of —— —— —— days' labor, $——
Cash.................................... ——
——
Total.................................... ——
In full for his water-tax, for the year ending March 1, 188—.
—— ——, *Water-master.*
PROVO CITY, UTAH, —— ——, 188—.

THE PUBLIC DOMAIN IN UTAH.

Within the Territory of Utah will be found several varieties of climate, ranging almost from semi-temperate in the north to semi-tropical in the south. The production of corn is limited; that of wheat and oats is large. Wheat brings 80 cents a bushel and runs from 25 to 30 bushels per acre. Oats bring from $1.16 to $1.60 per hundred pounds. Potatoes will give 300 bushels to the acre. A farm of 40 acres is quite sufficient for profitable cultivation. In the southern portion of the Territory the raising of fruit is claimed to be a success. Artesian water is found in several counties and over large areas.

The disposition of the public land domain in Utah for the past twelve fiscal years outside of mineral lands has been 2,681,605.96 acres. The percentage of Utah in farms is 1.92 of the whole. The entire arid region has but 2.85 per cent. Of tillable land Utah has (whether or not there be water for the same) 45.5 per cent. of its whole area. Of grass it has 18 per cent; of wood-land but 3 per cent. The unproductive area is set down at 11.4 per cent. of the whole. The question of reclamation in Utah then is, as elsewhere, one of mountain precipitation, of subterranean supply, and of artificial water storage and subsequent distribution. The rain-fall ranges from 7 to 17 inches per annum. The snow-fall is from 5 to 25 feet. In the mountains the precipitation is as 3 to 1 in quantity over the lower lands. The average yield of corn per acre is given at 22.5, of wheat at 17.8, and of oats at 26.3 bushels—an average which is close to the normal mean for the whole country. With these figures, it is evident that Utah holds larger promises than its past has achieved.

The most expensive thing in connection with an irrigating work in Utah, as elsewhere, is the main head, where the water is taken from the stream. Sometimes the channel is taken sufficiently far up the cañon to tap the stream without a dam, but in other cases it is found the lesser of two expensive works to dam the stream at a lower point rather than undertake the heavy quarrying or tunneling required higher up. The dams are of various kinds, according to circumstances, but that known to engineers as "the mud-sill" is mostly built over broad, shallow streams, and "the crib" used for deeper and narrower torrents up the cañons.

The usual plan of irrigation is to go well up the cañons and start a channel 10 feet wide by 4 feet deep, and carry this along the side of the cañon, and then around the side of the main range so as to command as large an area of level land as possible. The ditching, except in the rocky portions at the head of the cañon channel, is done by plow and scoop, one of the lightest of the latter implements, worked by a pair of mules, being invariably used. There are two 30-mile-long main ditches led along each side of the Jordan, and one 35 miles long is conducted from a mountain cañon in the direction of Provo, along the foot of the range towards Salt Lake City, thus providing water for a considerable area of country under the ditch.

Each acre of land brought within the influence of the canal is increased in value, and the $10-shares go up in the market. The water enables the working farmer to pay his passage-money back to the Mormon-Church, together with the tithe of all he raises, and further the expenses of his maintenance advanced to him during the construction of the ditches; and yet, after paying all these charges, in addition to, say, 10 cents an acre for maintenance of the ditches, he makes money. Each share in the Provo ditch, for instance, costs $10. That represents an acre of land, with a perpetual water right. Without the water right the land was absolutely valueless. It is now quoted at from $25 to $60 per acre, according to situation.

CONDITIONS AND POSSIBILITIES.

In 1875 there were in the twenty organized counties 2,095¼ miles of principal canals, costing $1,918,174, and 4,888¾ miles of tributary canals, costing $503,320. This was a total construction of 6,984 miles of canals and ditches, at a cost of $2,421,494. The total cultivated area within the district "under water" was 302,766 acres, of which 106,184 acres did not require the application of water at all. Mr. Caine, Delegate in Congress from Utah, under date of December, 1884, estimated that there were in the four most prosperous counties of that Territory irrigation (main) canals, as follows:

Counties.	Main canals.	Estimated cost.
	Miles.	
Weber	165	$300,000
Utah	150	250,000
Cache	175	550,000
Salt Lake	190	1,250,000
Total estimate	680	2,350,000

CLIMATOLOGY OF UTAH.

Prof. Marcus C. Jones, of the Deseret University, at the request of Governor Thomas, presented, in 1889, to the Senate Committee on Irrigation, among other papers, the following review of the Territory:

> The annual rain-fall of this Territory will not exceed 8 inches per annum, and were it not for the lofty mountains storing up the water in snow the Territory could not be inhabited. Therefore the settlements are to be found along the streams which are fed by the snow, and they are located chiefly at the bases of the mountains, though running out into the valleys as far as there is water.
>
> The Wasatch, rising over a mile above the valleys, run from north to south through the Territory, a little west of the middle, till they reach Iron County, where they turn to the southwest and fade away in Nevada. Their average height will not fall far below 10,000 feet above the sea.
>
> Nearly east of Salt Lake City the Uintahs, still loftier than the Wasatch, abut on them and run eastward till they pass out of the Territory. These are so close to the northern edge of Utah that we get little benefit from them, while to the south of them is an Indian reservation. Nearly due east of Utah Lake, and about 40 miles from the Wasatch, the Coal range starts from the Uintahs and runs southward parallel with the Wasatch for 160 miles, when it joins them at Panguitch Lake. These three ranges form the water-shed of Utah, the Coal range and the Uintahs forming the rim of the Great Basin, while the Wasatch performs a similar part below Panguitch.

The Wasatch and Uintahs are narrow, lofty, and rugged, while the Coal range is younger, lower, and broad. The Coal and Wasatch inclose between them some of the most fertile valleys of Utah. The Wasatch reach their culmination near Salt Lake City, and, aided by Great Salt Lake, give the greatest water supply in the Territory. The streams from this source irrigate the bulk of the cultivated area of Utah.

For ease in comprehension Utah may be divided into three divisions, the moist counties, whose rain-fall exceeds 12 inches per annum, the dry counties, with a rainfall of 6 to 12 inches, and the hot counties, with a slight rain-fall and great heat.

The moist counties are Cache, Box Elder, Rich, Morgan, Weber, Davis, Summit, Salt Lake, Utah, Wasatch, Uintah, San Pete, Sevier, and parts of Emery, Garfield, Pi Ute, and San Juan.

The dry counties are Tooele, Juab, Millard, Beaver, Iron, and parts of others.

The hot counties are Washington, Kane, and parts of San Juan, Pi Ute, and Garfield.

THE MOIST COUNTRIES.

Cache County is situated in the middle of the northern end of the Territory, at an elevation of 4,533 to 5,000 feet above the sea. All the arable land is in Cache Valley, which lies between two ranges of mountains, the Wasatch forming the eastern boundary. The water supply is 420.13 cubic feet per second, and comes from eight streams and rivers. The whole supply will be in use next year. The area of the county is 633,600 acres, of which 43,154 were cultivated this year. One thousand seven hundred and ten acres were dry-farmed, and 14,355 acres of crops were lost by lack of water. There are forty canals reported, aggregating 110.5 miles. The irrigating season is 122 days long, and land is irrigated 35 hours per year. The duty of water is less than a cubic foot per second to 100 acres. The average depth of snow in the mountains is 3 feet. The committee report water storage as the only means of increasing the cultivated area, since there are more than 420.13 cubic feet per second running to waste for 243 days, enough to irrigate from 50,000 to 75,000 acres. Many good reservoir sites are mentioned, but details are not given. It is probable that artesian wells can be obtained in some parts of this valley.

Box Elder County.—This lies in the northwest corner of the Territory. The eastern part is very fertile and well supplied with water, but the western and greater part belongs to the dry counties. The area is 2,767,360 acres, of which 53,280 acres are cultivated, and of these latter 19,190 acres are cultivated but not irrigated. The elevation of the fertile parts is 4,215 to 5,000 feet above the sea. There are 12 canals reported, length 76 miles. A branch of the Great Bear River canal is to irrigate a large area in this county. Large quantities of fruit are raised here, and still greater amounts of small grain and hay. The extensive valley of the Bear has been for half a century the recruiting place for overland travelers by team. Artesian wells are very numerous and add greatly to the productive area. Water storage is the main question here. Five reservoir sites are reported in detail, and several others in general. Bear Lake is the natural reservoir for this and Cache County, and will store all the water that will ever flow into it.

Rich County.—This lies at an elevation of 6,000 to 7,000 feet above the sea, in the northeast corner of the Territory, at the eastern base of the mountains. It is high and cold, raising only small grain, hay, etc. It lies all in one valley; is watered chiefly by the Bear River and some streams that flow into the lake. This land takes little water to mature crops, and much produce is raised without irrigation. The soil is sandy. The area of the county is 497,280 acres. There is no report from this county.

Weber County.—This lies south of Cache, extending from Great Salt Lake through the Wasatch to the headwaters of Ogden River. The best portion lies in Salt Lake Valley at an elevation of 4,315 feet, while Ogden Valley, lying along that river, lies east of the Wasatch and is more elevated. The water supply of the county comes from 17 streams and rivers, flowing 323.66 cubic feet per second. There are 117,600 acres under cultivation, of which 29,400 acres are fully irrigated, while the rest is partially irrigated or dry-farmed. The soil is sandy, with clay close to the lake. Five thousand one hundred and seventy-two acres are irrigated from artesian wells. The duty of water is one cubic foot per second for 80 acres, or thereabouts. There are 25 canals, length not given. The irrigating season is 122 to 152 days long. This county is one of the most productive that we have, raising all kinds of fruit and produce that is raised in the Great Basin. The only solution of the water question here is storage. There are over 323.66 cubic feet per second going to waste for 213 days, enough to irrigate 30,000 to 40,000 acres. One reservoir site is reported, of small dimensions, while others are reported from Huntsville and Wheeler's Creek, and there are numerous sites at the head of the Weber.

Davis County.—This county lies wholly west of the Wasatch, being south of Weber and north of Salt Lake Counties and between them and the lake. There is very little waste land in this smallest county in the Territory, whose arable land lies wholly in Salt Lake Valley. This county is well watered close to the mountains by numerous small streams, and lower down by multitudes of artesian wells. Many acres are not irrigated. This county is full of orchards, gardens, and fields, while roots, small grain, and hay are raised in abundance. The elevation is 4,215 to 4,500 feet above the sea. The area is 160,000 acres. The soil is sandy but with clay near the lake. There is no report from this county.

Morgan County.—This lies directly east of Davis, on the east side of the Wasatch, and occupying Weber Valley as far as Croyden. This is elevated nearly 6,000 feet above the sea, and is only adapted to small grain, root crops, and hay. The water supply is fair and the opportunities for storage good. The area is 675,840 acres, of which about 10,000 acres are cultivated. The soil is chiefly sandy.

Summit County.—This county lies almost wholly in the upper valley of the Weber, and includes Parley's Park. It occupies the angle between the Wasatch and the Uintahs, and lies north of the latter. Its ultivated land is elevated 6,000 to 8,500 feet above the sea. It is cold and best adapted to small grain and hay. Much produce is raised without irrigation, and only a small amount of water is required per acre to mature crops. The valley of Weber is a succession of green fields for many miles, while on Chalk Creek and other tributaries are scattered many farms. The area of the county is 2,419,200 acres, of which 7,500 are under cultivation. This county also reports storage of water as the only means of increasing its cultivated area. Deep artesian wells might be successful here. The soil is sandy.

Salt Lake County.—This county lies between the south end of the lake and the Wasatch Mountains, occupying all of the southern end of Salt Lake Valley and lying between the Oquirrh and Wasatch Mountains. This county takes the lead in water supply and position, since the valley is 10 miles wide and 20 miles long, runs north and south, and is watered by the Jordan and by numerous large streams that flow down from the heart of the Wasatch. There are also a few streams flowing from the Oquirrh Mountains. Throughout the lower part of the valley thousands of artesian wells are flowing. The soil is sandy in the upper and clayey in the lower part of the valley. The elevation is 4,215 to 4,500 feet above the sea. The area of the county is 614,400 acres. The cultivated land is 38,587 acres. The water supply is 365.5 to 425.5 cubic feet per second, all in use. The irrigating season is one hundred and twenty-two to one hundred and fifty two days long, and the duty of water is about 1 cubic foot to 80 or 100 acres. The rain-fall during the irrigating season is only 7.882 inches, being more than double that in many other parts of the Territory.

There are 13,668 acres of lucerne raised; hay, 2,215 acres; small grain, 13,566 acres; roots and vegetables, 3,470.5 acres, and fruit, 1,628.5 acres. There are thirty-seven canals with an aggregate length of 213.8⅜ miles. There is enough water running to waste outside of the irrigating season to redeem 44,000 acres. There are eleven reservoir sites in the mountains reported in detail, aggregating 50,250,000 cubic feet, and several others of good size not reported. There are four sites reported in the valleys, and one of them, Utah Lake, if raised 2 feet would irrigate 53,000 acres, and if raised 5 feet would irrigate 133,000 acres. But this lake can never be filled in a dry season; the total inflow last winter was only enough to raise the lake a foot, and for other reasons hereafter given it will never cut much of a figure as a reservoir. The average depth of snow in the mountains is 4 to 10 feet. The relative humidity for the year is 48.3 per cent.; during the irrigating season it is 42.3 per cent. The annual temperature is about 51.2 degrees.

Utah County.—This county lies chiefly in the beautiful Utah Valley with its large fresh-water lake in the center, 80,000 acres in area. Most of the arable land is in this valley, but there is considerable arable land on the Spanish Fork River. The elevation is about 4,600 to 4,800 feet above the sea. Though it is some higher than Salt Lake Valley it is nearly as warm, because of sloping toward the sun. The area of the county is 1,344,000 acres, of which 69,126 acres are cultivated. The irrigating season lasts about 122 days. The duty of water is reported as 40,000 cubic feet per year, but it is probably not less than 1 cubic foot per second for 100 acres. The water supply comes from fourteen streams and one river, whose flow in July was 308 cubic feet per second. There are sixteen canals reported; length, 66.2 miles. There are many artesian wells in the valley. They lost 28,985 acres of crops this year by lack of water. There are eight reservoir sites given in detail in the mountains and two in the valleys; capacity 791,000,000 cubic feet. There are five additional sites given in the valley and nineteen in the mountains; capacity not specified. Enough water runs to waste to irrigate 50,000 acres. About the same amount of rain falls here as in Salt Lake Valley. The average depth of snow in the mountains is 4 feet. The soil in this county is mostly sandy. Along the Spanish Fork River are many farms with an elevation of 5,500 to 6,500 feet above the sea whose supply of water could be greatly increased by deep artesian wells.

Wasatch County.—This lies east of the Wasatch, and the inhabited portion is west of the Coal range, being south of Summit and east of Utah County. The settled part is a triangular valley at the eastern base of the Wasatch, called Provo Valley, since it lies along the Provo River. This is some 6,000 feet above the sea, has 18,000 acres of cultivated land, and 32,000 acres that could be reclaimed by more water. The water supply is not given, but one-half the crops were lost this year by lack of water. There are 14.5 miles of canals reported. Five reservoir sites are reported, capable of irrigating 14,000 acres. This valley raises small grain and hay chiefly. Water storage is a necessity if the present acreage is to be preserved, to say nothing of extending it. The greater portion of this county of 1,344,000 acres lies east of the Coal range on the reservation. There are hundreds of acres there that produce abundant crops of hay when stock is kept off from them.

Uintah County.—This county is situated east of Wasatch, Summit, and Emery Counties. It is mostly an Indian reservation; but just south of the Uintahs is a small cultivated area not on the reservation. The area of the whole county is 4,000,000 acres. The cultivated area is 8,932 acres. The soil is partly sand and partly clay. The elevation of Ashley Valley runs from 4,400 to 5,000 feet. The irrigating season is from 178 to 198 days long, and the duty of water is given as 20,000 to 50,000 cubic feet per acre, but this is doubtless far too small. It takes a trifle more water for clayey than for sandy soil. It takes the same amount of water for small grain as for lucerne, a trifle more for root crops, and one-half as much for orchards. There were 970 acres of crops lost this year from lack of water. The average depth of snow in the mountains is 6 feet. Several good reservoir sites are mentioned. The supply of water in Green River is unlimited, and much land could be reclaimed by proper dams in this river. The supply of water on Ashley and Brush Creeks is quite limited, but could be greatly increased by reservoirs.

San Pete County.—This county occupies an elevated valley between the Wasatch and Coal range, and south of Utah County. It is the valley of the San Pitch River and a part of Thistle Valley. The former runs southward from the head of Thistle Creek for 45 miles till it joins the Sevier Valley. The elevation is perhaps a thousand feet or more higher than Salt Lake Valley, and the rain-fall is less. The water supply come from both sides of the valley in numerous small streams, but the greater number come from the east. This has been called the granary of Utah. The chief product is small grain. The irrigating season lasts 107 to 183 days. The duty of water is about 1 cubic foot per second to 90 acres. Each acre is irrigated 120 hours. Many acres of crops were lost this year through lack of water. The average depth of snow in the mountains is reported as 6 feet. Several reservoir sights are mentioned. The area of this county is 1,164,800 acres. The amount under cultivation is not reported.

Sevier County.—This county occupies the southern part of the great valley which lies east of the Wasatch and west of the Coal range, running from Thistle on the north to Panguitch on the south. This great valley, over 125 miles long, is called the San Pete on the north and the Sevier on the south. It is lowest in the middle where the southward flowing San Pitch and the northward flowing Sevier Rivers unite, and breaking through the Wasatch pass out westward upon the desert in Millard County. The only arable land in this county lies in the Sevier Valley, which in this county is several miles wide and 50 miles long. It is watered chiefly by the Sevier River, but there are many small streams and springs coming from the mountains on either side. The river measured 70 cubic feet per second at Joseph City on July 26, 1889. No other measurements are reported. There were reported eleven canals aggregating 107.5 miles in length. The area of the county is 993,280 acres, of which 25,000 acres are under cultivation; all but 7,000 acres are watered by the Sevier River; 100,000 acres could be irrigated if there were more water. There are 2,634 acres of lucerne raised, 11,982 acres of small grain, 710 acres of root crops and vegetables, and 178 acres of orchards. The elevation of the lower part of the valley is about 5,500 feet and the irrigating season is 244 days long. Some fruit is raised here. The upper part of the valley is from 6,000 to 7,000 feet above the sea, the irrigating season is 122 days long, and small grain and hay are the chief products. The soil is sandy and very productive. There are none of the thinly populated counties that have such possibilities before them as this; for there is enough water to irrigate the whole valley if it is properly stored. The depth of snow in the mountains in winter is about 6 feet. Six reservoir sites of great capacities are reported in the mountains. All the present water supply is utilized. Deep artesian wells are possible in some parts of the valley.

Pi Ute County.—The cultivated portion of this county lies in or near the heart of the Beaver Mountains, south of Sevier County, and at the junction of the Coal range with the Wasatch. The valleys are elevated and cold, being 5,400 to 7,000 feet above the sea. The irrigating season never exceeds one hundred and seventy-three days. The duty of water is not more than one cubic foot to 100 acres. The land is irrigated from twenty to forty-eight hours per annum. The water supply is 217 cubic feet per second; comes from eleven creeks and rivers, and in some localties is not all in use, while in other places 400 acres were lost and many more injured by lack of water. There are 31 canals. Ten reservoir sites are reported of such capacity as to irrigate

15,000 additional acres, more land than there is to cultivate. The average depth of snow in the mountains is 4 to 5 feet. The area of the county is 2,368,000 acres. The cultivated area is 12,135 acres, lying in Sevier, Grass, and Rabbit Valleys. But little fruit is raised in this county.

Garfield County.—The western part of this county also lies in the heart of the Beaver Mountains, and its cultivated valleys are all elevated 5,835 to 6,273 feet above the sea and cold; best adapted to hay and grain. The irrigating season lasts ninety-seven days, and the duty of water is slight; the land is irrigated but twenty-five days during the year. The water supply is not given. There are 34 canals. The area of the county is 2,892,800, of which about 5,000 acres are cultivated. Four reservoir sites are definitely reported, and many others are mentioned; enough to irrigate several times all the arable land in the county. Some of these sites could be used to help out Kane and Washington Counties.

THE DRY COUNTIES.

The larger part of these counties is arable land, and can never be reclaimed because of being destitute of any water, either present or prospective, while the eastern edge of these counties might almost be classed with the moist group.

Box Elder County.—This county lies in the northwest corner of the Territory and is the least arid of them all. The western portion has a few farms and some meager streams, while that portion next to the lake is susceptible of artesian wells and is quite productive. The mountains in this portion are so low and lose their snow so early that water storage is out of the question.

Tooele County.—This county lies west of Great Salt Lake and Salt Lake County. It is very large, containing 4,140,800 acres, of which only 6,250 acres are cultivated, and these lie chiefly in one valley (Tooele). This valley is a broad one, lying between the Oquirrh and Aqui Mountains, from which it receives its water in eight small streams aggregating 78¼ cubic feet per second. These mountains do not rise high enough to give water all the season. This valley is being greatly developed by artesian wells. Rush valley is a magnificent one, being the southern extension of Tooele Valley. There are 200,000 acres that could be redeemed here alone, but there is no surface nor artesian water to be had. Reservoirs might catch some water. Skull Valley is another large tract lying directly west of the Aqui Mountains This is capable of artesian wells, and has a small supply of surface water. It is undeveloped. On the western edge of the county near Deep Creek is some cultivated land. There are 1,000,000 acres of good land that could be redeemed if there were water for it, but by fully developing all resources by storage and otherwise 100,000 acres is an outside limit of the acres that will ever be cultivated in this county with the present rain-fall. The elevation of the valleys is 4,400 to 5,000 feet above the sea. All kinds of fruit and produce can be raised here that are raised in Salt Lake County. The duty of water is 1 cubic foot per second to 80 acres, and the irrigating season runs from 122 to 200 days. Several good reservoir sites are reported. The average depth of snow in the mountains bordering Tooele Valley is 3 feet. The soil is so gravelly near the mountains that fully one-half of the water is lost by seepage before it gets to the fields. Water storage and fluming the canals are the crying needs of this county.

Juab County.—This county lies south of Tooele and runs from the Wasatch to the western boundary. The area is 2,457,600 acres, and fully one-half of it is level land that could be redeemed by water, but outside of artesian wells there is no hope for most of this county. Four thousand acres are reported under cultivation beneath the shadow of Mount Nebo. All kinds of fruit and grain are raised here that the Great Basin produces. The elevation of the valleys is from 5,000 to 5,500. The average depth of snow in Mount Nebo is 3 feet. Several good reservoir sites are reported. Nearly one-half of the crops were lost this year by lack of water. Water storage and artesian wells are the only hope of this county.

Millard County.—This county lies south of Juab and runs from the Wasatch to the western boundary. This is one of the largest counties in the Territory and has the largest amount of arable land of any, if there were only water for it. The area of the county is 4,492,800 acres, and over one-half of it is good land. Artesian wells are being developed in this county, but generally the flow is so slight that the water is valuable only for drinking. The settlements lie along the western base of the Wasatch and along the Sevier River. They are from 5,000 to 6,000 feet above the sea, and produce large quantities of fruit, small grain, and lucerne hay. The irrigating season runs from 90 to 122 days. There are 13,500 acres reported as under cultivation; 1,000 acres were reported as lost and much more as injured by lack of water this year. The soil is sandy near the mountains and clayey in the Sevier Valley. There are 42 miles of canals reported. Water storage is not only an imperative necessity in this county, but it is practicable. Much water runs to waste in the Sevier River; probably triple what is used. There are many good sites along the river where from 1 to 3 square miles of water several feet deep could be held back. Back of Scipio a natural lake, now used as a reservoir, could hold 5 square miles of water of considerable depth. It is said that the Sevier River could be turned into it. There are several good sites in the Wasatch.

Beaver County.—This county has an area of 1,689,600 acres, of which one-fourth is good land; 9,500 acres are reported under cultivation. This county lies south of Millard and runs from the Wasatch to the western boundary. The upper valleys are 6,000 and the lower about 5,000 feet elevation. The irrigating season lasts ninety-one to one hundred and twenty-two days. The land is irrigated twenty-nine to thirty-two hours per year. There are 45 canals; length not given. The settlements lie chiefly along the Beaver River and its tributaries. The average depth of snow in the mountains is reported as 8 feet. The Wasatch here rises to a great height and snow lies on the mountains all the year round; 25 reservoir sites are reported in detail, aggregating 17 square miles, sufficient to irrigate 20,000 acres at least; about 10 of these reservoirs are in the valleys and the remainder in the mountains.

Iron County.—This county lies south of Beaver, on the rim of the Great Basin, running from the Wasatch to Nevada. Its area is 2,102,400 acres, and nearly half of it is arable land, some of it capable of artesian wells, but most of it destitute of water; 6,997 acres are reported under cultivation. The irrigating season is given as 142 to 269 days. The elevation of the valleys runs from 5,400 to 6,100 feet above the sea. The duty of water is given as 1 cubic foot to 65 acres in the more arid valleys and from 160 acres to more than double that in the moist valleys. The water supply comes from 8 small streams, capacity 67.63 cubic feet per second. The land is irrigated from fifteen to forty-two hours per year. If the water could be saved, from 10,000 to 20,000 acres could be redeemed; 14 reservoir sites are reported in detail. Water storage is the only means of developing the agricultural resources of this county. The soil is chiefly clay.

Emery and Uintah Counties.—To this group belong parts of these two counties, which lie between the Green and Grand Rivers. There are many thousands of acres of clayey soil that could be reclaimed by great canals running from these rivers, whose unlimited water supply, greater than all the rest of the Territory put together, will run to waste without assistance is given in constructing such canals. There is no part of the Territory that needs developing more than this. Very deep artesian wells might be successful here.

Emery County.—But a small part of this county belongs to the Dry Counties, still nearly all of the cultivated area lies in that section on the extreme western side of the county. This lies directly east of San Pete and Sevier Counties at the foot of the Coal range. The rain-fall does not exceed 10 inches per annum. The water supply comes from four creeks and one river, breaking through the precipitous eastern face of the Coal range in narrow cañons. The flow of water is 171.15 cubic feet per second. The area of the county is 5,603,680 acres. The cultivated land is 14,825 acres. The soil is a very refractory clay. The duty of water is 1 cubic foot to about 35 acres. Castle Valley is 4,500 above the sea, and the irrigating season is 229 days long. Little Grand Valley is 3,900 feet above the sea, and its irrigating season is 244 days long. There are 34 canals; length not given. One-quarter of the crops was lost this year through lack of water. All the water is in use. The average depth of snow in the mountains is 4 feet. Twelve reservoir sites are definitely reported, and many others are mentioned. There is enough storage to use double the total water supply. Probably 10,000 to 15,000 acres more could be irrigated by saving the waste water. Great suffering often results from scarcity of water in this county. All kinds of crops are raised in this county, even sugar-cane, fruit, pea-nuts, etc. Figs could be raised in the hotter portions.

THE HOT COUNTIES.

These counties are far more arid naturally than the dry counties, since they are farther from the lofty mountains, and most of the arable parts are 2,000 or more feet lower, lying in deep valleys shut out from winds and surrounded by great fields of lava with red hills and a red, sandy soil of unknown depth. The heat here is almost unendurable and the rain-fall is almost nothing. This region is valuable for the fruit and cotton that it raises.

Washington County.—This county is situated in the southwestern corner of the Territory. The area is 1,649,920 acres. Of this, 18,892 acres are cultivated. These are situated along the Virgin River or its tributaries chiefly. It is estimated that 18,900 acres could be redeemed by an increase of the water supply. The lower valleys are 2,700 and the upper 4,000 feet above the sea. In the lower valleys the irrigating season is 197 to 228 days long, in the upper 122 to 177 days. The water supply comes from the Virgin River, four streams and many springs, capacity 191.8 cubic feet per second. In the lower valleys the land is irrigated 84 to 90 hours per year, and the duty of water is 1 cubic foot per second to 20 acres. In the upper valleys the land is irrigated 26 hours per year and the duty of water is 1 cubic foot per second to 60, 80, and 128 acres. There are 31 canals; length not given. One-third of the crops were lost this year by lack of water. It is probable that water enough could be stored to redeem most of the arable land in this county. Vast quantities of water go to waste in the Virgin River in the winter and flood time in spring. The depth of snow in the mountains is 2 to 6 feet. This county raised 30,000 pounds of cotton last year. The Sultana seedless grape is grown here and produces from 3,000 to 5,000 pounds of the finest quality of raisins. Both the hard and soft shell almonds are raised in quantities here as well as figs. It is believed that oranges can be raised here. Olives are grown in this county. Peaches and apricots from this region are very fine. They raise 4 to 5 crops of lucerne per year. A crop of small grain and another of corn are raised from the same land.

Kane County.—This county is more rugged than Washington and more elevated except along the Colorado River. It lies east of Washington. The area is 2,659,200 acres, of which 1,825 acres are cultivated, and 13,350 acres are said to be arable. The irrigating season is 182 days long, and the duty of water is from 37½ to 75 acres to the cubic foot per second. The water supply, exclusive of the limitless Colorado River, is 31 cubic feet per second. There are nine canals; length not given. The crops are greatly damaged by lack of water. Sufficient reservoir sites are reported to irrigate all the arable land in the county. The average depth of snow in the mountains is 4 feet. The crops in this county are much the same as in the foregoing, though more small grain and hay are raised in proportion to the area cultivated.

San Juan County.—This county lies in the southeastern corner of the Territory. Most of it is now proposed to be made an Indian reservation. Its area is 5,809,920 acres. There is a narrow strip of land along the Colorado and San Juan Rivers that will produce the crops of Washington County, and has an unlimited water supply. Most of the cultivated area is 5,000 feet above the sea, near the La Sal Mountains. There are 1,025 acres cultivated. Dry farming is successful in some localities in the mountains. There are good facilities for storage of water.

Other counties.—Small parts of Garfield and Pi Ute Counties situated along the Colorado are capable of raising the same products as Washington County.

To sum up we find there are about 500,000 acres of land under cultivation at the present time. This area could be doubled from the present canals if there were more water and by new canals, etc. The various counties estimate that about 3,500,000 acres could be redeemed. This is doubtless three and a half times too large. The average depth of snow in the mountains is 4 feet. The length of the irrigating season in the moist counties is one hundred and fifty-two days; in the dry counties it is about the same in cultivated areas; in the hot counties it is about two hundred days. The returns are very unsatisfactory in this respect and must be wholly revised. The duty of water is about 80 acres to the cubic foot per second in the moist counties, in the dry counties it is uncertain, and in the lower hot counties it is about 20 acres. The water supply is about 3,000 cubic feet per second for the moist counties, 250 for the dry counties, and 250 for the hot counties; total 3,500 cubic feet per second. This is probably our minimum water supply throughout the dryest years in the counties reported. If we were to add the supply in the Green and Grand Rivers this amount would be more than double. Almost all of the present supply is appropriated during the irrigating season and our Territory must remain at a standstill without water storage. There are 150 reservoir sites reported in detail and nearly as many more mentioned. They vary in capacity from 130 square miles to 1 acre, and from 2 feet to 100 feet deep. About one-third of the crops were lost this year through lack of water.

Utah, Nevada, and Arizona are the most arid portions of the United States, and therefore the preservation and economical use of all their water supply is an imperative necessity. To show how we differ from Colorado and the East, I have prepared a diagram of the average monthly rain-fall of Salt Lake City for thirty-three years, and of Denver, Colo., and Des Moines, Iowa, since the beginning of observations there

During the irrigating season here Des Moines, a place where irrigation is not necessary, has a rain-fall of over 2 acre feet and Denver almost 1 acre foot, while Salt Lake has less than two-thirds of an acre foot, which would make a difference of about 11,000 cubic feet to the acre, which must be made up by that much more water from the streams to irrigate our land as well as that of Colorado is irrigated. But during the same period the relative humidity of Denver is 3 degrees higher and the temperature 2 degrees lower, which would greatly increase the amount of water required to irrigate an acre of land in Utah in proportion to that of Colorado. Besides this, Denver is nearly 50 miles from the crest of the mountains, from which a part of its moisture is derived, while Salt Lake City is but 10 miles and has a lake of 2,000 square miles in area within 7 miles on the other side. These things make Denver fairly representative of northern Colorado in general, while they show Salt Lake City as the place with at least 50 per cent. more rain-fall than the rest of the Territory (save the mountains themselves) and with a very abnormal humidity. Therefore what applies to Salt Lake in the great amount of water required per acre will apply with redoubled force in the dry and hot counties.

We have had evaporating pans located in various parts of the Territory for the last two months, and though these were of necessity placed out of the reach of the wind the evaporation averaged three-tenths of an inch per day, often running up to five-tenths of an inch. Had they been placed where the wind could have reached them the evaporation would have equaled 15 inches per month. The enormous drain upon our water supply can therefore be well understood. This militates against shallow reservoirs in the valleys. If Utah Lake were raised 3 feet its water would all be evaporated during the irrigating season if none flowed in or out. Enough to irrigate 83,000 acres would go up in the air. From records kept in the mountains the evaporation there during the same period was only eight-hundredths of an inch, and never exceeded seventeen-hundredths per day. Therefore reservoirs in the mountains are at least four times as valuable as those in the valleys. We do not yet know the rain-fall in the heart of our mountains, but it will not fall far short of 40 inches nor more than 60 inches per annum. It should be observed that though we have 2 inches more rain-fall in Salt Lake than in Denver, yet but 46 per cent. of it falls during the irrigating season while 73 per cent. of Denver's rain-fall comes when it is needed most.

The possibility of reclaiming Utah by artesian wells has been greatly overestimated. All the wells so far obtained have been found in some one of the basins of the ancient lake of which Great Salt Lake is the saline remainder; the area of that lake never exceeds 18,000 square miles. The clay sediment from that lake makes the impervious cap of those subterranean reservoirs, whose rims are but slightly elevated above the villages, and the reservoirs are fed from the bases of the mountains where the surface water runs over the gravel débris between the mountains and the clay rim. The average depth of these artesian wells in Salt Lake Valley is about 100 feet, in Utah Valley 200, and in Tooele about the same. In Millard County a few wells have been driven with a depth of about 200 feet and a flow of one-half to 10 gallons per minute through 1¼ inch pipe. Since no solid rock is struck in driving these wells they are very liable to clog up in a few years. The flow in Salt Lake Valley will not average 25 gallons per minute, though some wells far exceed that. A well flowing 5 gallons per minute will irrigate an acre of ground.

ARIZONA AND ITS IRRIGATION CHARACTER.

Turning southward, Arizona is found to be making considerable progress. The southern, or Gila Valley portion of the Territory, and its smaller central valleys, offer a considerable area for the farmer when irrigation is applied. The difficulties of the problem are found not only in the newness of the region, as to settlement, but in the want of system and the confusion of ideas as to the lawful use and control of water. The Mormon system would probably bring about in both Arizona and New Mexico the same admirable results that it has secured in Utah. It is estimated that there are in the Territory about 2,800,000 acres of land of the best quality, with surface water sufficient to irrigate the same by a reasonable expenditure on ditches. Of the above area not quite 300,000 acres are in cultivation. There are at least 10,000,000 acres of rich land that could be reclaimed by means of artesian and other wells, if they can be obtained.

For convenience of arrangement in considering its agricultural capabilities, Arizona may be divided into: (1) The Colorado Valley; (2) the valley of the Gila and those of its tributaries, including the Salt River as far north as the thirty-fifth parallel; (3) the Santa Cruz Valley, the isolated locations of Pinal and Pima Counties, and the vicinity of the New Mexico line; (4) the Colorado Chiquito Valley; (5) the southwestern portion of Yavapai County, surrounding Prescott, and the valley of the Rio Verde, with its tributaries.

In one of Lieutenant Wheeler's reports of exploration in Arizona, California, and Nevada, a comparison is made between the capabilities of certain portions of the Territory and those States, which brings to light some important facts. The Arizona portion compared is bounded in longitude by the meridians of 111 degrees and 113 degrees 45 minutes, and in latitude by the parallels of 34 degrees and 35 degrees 40 minutes, which include the southwestern portion of Yavapai County and a small strip of Mohave County, by no means the best agricultural region of the Territory, and scarcely up to the average. This is compared with the eastern portion of southern California, and the southern portion of Nevada, in the same latitude:

	California and Nevada.	Arizona.
	Per cent.	*Per cent.*
Agricultural, irrigable, and arable land	2	25
Timber	6	10
Grazing	88	30
Barren	4	35

In the Colorado Valley the soil is rich in the chemical combinations requisite for fertility, and only in small patches contains too large a proportion of clay. In some places it has also small amounts of chloride of sodium and sulphate of lime. The fertilizing reddish mud resembles that of the Rio Grande and of the Nile, and its quantity varies from 0.1 to 0.5 per cent. (1–1000 to 1–200) of the water, which is good to drink even when considerably colored by the mud. As compared with the aboved-named rivers, it contains less potassa, more phosphoric acid, and much more carbonate of lime, the presence of the latter valuable ingredient being due to the immense limestone beds through which the river flows in the upper part of its course.

The following table (mud from the Colorado having been collected) exhibits a comparative analysis of the mud of these rivers:

	Colorado.	Rio Grande.	Nile.
Hygroscopic water	3.27	1.890	....
Chemically bound water, soluble in hydrochloric acid	1.14	3.122	....
Potash	0.103	0.284	0.166
Soda, with trace of lithia	0.074	0.064	0.022
Lime	....	1.479	1.725
Carbonate of lime	12.50	5.190	....
Magnesia	0.69	0.080	0.046
Oxide of iron	....	3.640	} 8.804
Alumina	2.26	1.308	}
Phosphoric acid	0.146	0.092	0.143
Sulphuric acid	Trace.	Trace.	Trace.
Oxide of manganese	Trace.	....	....
Insoluable in hydrochloric acid	78.1	82.55	....

As to the extent to which the Colorado River could be rendered available for irrigation, it has been appropriately remarked by geologists that the country bordering on the Colorado is the most conspicuous example in the world of overdrainage; for nowhere else do we find a stream that for hundreds of miles cuts its way 500 to 600 feet deep through solid rock. The Colorado, supplied by streams from the mountains, where rain and snow are abundant, cuts its way through a rainless, and therefore desert, region, in which the only changes are those resulting from the direct action of the atmosphere, so that no appreciable débris of any kind is furnished to fill up the excavations continued through millions of years, and only limited by an approximation of the level of the river-bed to that of the waters of the Gulf of California.

Lieutenant Wheeler estimates the area of land drained by the Colorado River and its tributaries to aggregate 242,065 square miles, mostly still owned by the Government.

The Salt River Valley is 25 miles in length by about 14 in width. With its estimated 250,000 acres of rich, alluvial soil, capable of producing 25 to 50 bushels of grain to the acre, it ought easily to support 50,000 inhabitants, if there were a sufficiency of irrigating ditches and artesian wells to fully utilize its natural capabilities.

The valley of the Gila, though cultivated along most of its course, is not available for semi-tropical productions in its upper part on account of October frosts. The White Mountain Indian Reservation (San Carlos) interferes with a continuous white settlement above Florence, as the lands of the Pimas and Maricopas do below it. These latter Indians have cultivated wheat, corn, pumpkins, melons, etc., for centuries, and have always been self-supporting, as well as the Papagoes, farther south, who, however, depend principally on stock.

The Gila bottom merges imperceptibly into the foot-hills, and has an average breadth of from 5 to 10 miles. Its soil is principally alluvial, and will produce two crops yearly. Irrigation is easily effected. The river averages 600 feet in width, and is 3 to 5 feet in depth when there is no rain-fall and no water from the mountains. The banks along the whole of this tract are so low and sloping as to afford unusual facilities for the construction of ditches. Excellent crops of wheat, barley, and vegetables are grown. In the vicinity of Florence is an extensive tract of rich bottom and second-mesa or table-land, on which are now grown the cereals, alfalfa, the sugar cane, and vegetables and fruits generally, including orange and lemon trees. Fruit culture in the Gila Valley is extensive. Cottonwood, ash, and locust are abundant. Farther up the valley the Pueblo Viejo has, with its tributary valley of Ash Creek and others, at least 100,000 acres of good farming land.

On the uplands and farther up the valley itself, near the line of New Mexico, the daily variations in temperature are much less and the frosts begin later. Still farther up its course, within the borders of New Mexico, the Gila River has upon its margins much good agricultural land. The bottom-lands generally are quite rich in potassa and phosphoric acid.

The valley of the Francisco River, a tributary of the Gila, near the line of New Mexico, is good for grazing and timber, and has in general a rich soil. The San Pedro River is a tributary of the Gila, its mouth being between Florence and San Carlos, and its source in the Huachuca Mountains, near the Mexican line. There is good land, good timber, and excellent range for stock. Considerable valley land is now under cultivation, and irrigation is generally required.

The Santa Cruz Valley, though smaller in extent, is equally productive in proportion to its area. It is more compact, and all of it is adapted to semi-tropical fruits, as well as to the vegetables of the temperate zone.

According to information received, about 250 miles of main canals have been completed during the past two years, or are under rapid construction. With the tributary feeders and laterals southern and central Arizona now has completed, or very nearly so at least, about 700 miles of irrigation works. As this Territory has always been considered one of the most unpromising in the dry and mountain regions of this country, these facts are of a cheering character. The most astonishing reports are made of the fertility of the areas "under water."

RAINY SEASONS AND PRODUCTION.

The physical configuration of Arizona shows it to be, as already stated, an overdrained region. This is in itself sufficient to account for the unquestioned aridity of a large portion of the Territory, but settlement and time are proving there, as well as elsewhere within our mountain area, that the supplies of water, with proper conservation and distribution, will be found more important and available than has generally been considered at all probable. In the narrow and precipitous valleys of Central Arizona there are natural reservoirs, of which, with comparatively little outlay, valuable storage basins may be created and force obtained to raise the water high enough for reaching extensive portions of the mesa or table-lands adjoining the river valleys. Several of the minor streams are known to sink, and their recovery and use for industrial purposes will be found a task not difficult to engineering skill.

There are two rainy seasons, in the winter and summer months respectively. In the summer the rains are often violent and torrential in character, disappearing almost as suddenly as they come. In April and May there are often neighborhood showers, seeming to be limited in area, as if the currents in their passage from the Southern Pacific, coming through the Gulf of California, were broken by the higher peaks and whirled in circular eddies over the sections visited. They are known by the Mexicans and Indians as "shepherd rains."

The population is rapidly increasing, especially in the southwestern and central portions of the Territory. The immigration into these sections aggregates 5,000 persons yearly, and the increase for the Territory for the last ten years will average fully 10,000 per annum. The returns from the different counties to the Territorial auditor for the present year show a total valuation of $27,231,424.47.

Arable land with water that sells at from $20 to $75 per acre is assessed at from $5 to $15 per acre. There are assessed 5,985,358 acres in the Territory, about 5,000,000 of which is embraced in the grant to Atlantic and Pacific Railroad, and assessed at 20 cents per acre, which is being sold at from $1 to $10 per acre. The entire valuation on land is $3,285,212.60, on landed improvements $1,931,440.83. There are assessed 552,718 head of cattle; the actual number in the Territory will fall a little short of 2,000,000. The estimated population is by counties as follows:

Yavapai	16,000	Cochise	14,000
Maricopa	16,000	Pima	14,000
Apache	12,000	Pinal	8,000
Mohave	5,000	Yuma	3,000
Gila	5,000		
Graham	12,000	Total	105.000

The lands covered by canals and ditches is in—

	Acres.		Acres
Apache County	6,900	Yuma County	40,000
Yavapai County	40,360	Pima County	7,500
Gila County	7,600	Cochise County	23,500
Pinal County	71,600	Mohave County	1,000
Graham County	47,000		
Maricopa County	321,000	Total	566,460

Of land requiring no irrigation the amount entered and occupied is estimated at 100,000 acres, lying principally in the counties of Apache, Yavapai, Graham, Pima, and Cochise, of which one-half has been cropped the present season.

The value of the agricultural product varies according to locality. In this valley the Salt River hay is baled at $5 per ton; in Yavapai and Apache Counties at $20 to $25. Barley is worth here 75 cents per hundred; in other counties from $1 to $2.50. Fruit here is worth from $20 to $40 per ton; in other counties from $40 to $200. Land in alfalfa or grain here gives a return of from $15 to $25 per acre; in other counties from $30 to $50. Fruit in this and the Gila Valleys gives a return of $100 to $200 per acre, and in other localties more or less according to yield. The value of product from every acre of land cultivated in Arizona can safely be placed at $30, which will be largely increased in the southern valleys as the orange, fig, grape, apricot, and other fruit-trees and vines now being planted come into bearing.

The value of the products of the Territory for 1889 was as follows:

Agricultural and horticultural	$9,207,000
Live-stock—horses, sheep, and cattle	6,000,000
Gold and silver	4,431,500
Copper	2,000,000
Lumber, wool, etc	1,500,000
Total	23,138,500

In the Territory the amount of land that can be reclaimed through a proper system of reservoirs and canals, conserving the storm water for irrigation, is very large, being variously estimated from 6,000,000 to 8,000,000 of acres, fully two-thirds of which, lying below the thirty-fourth parallel and not in the mountains, can be made available for the cultivation of those citrus and deciduous fruits that make horticulture most profitable in all semi-tropical countries.

Mr. Farish, immigration commissioner, from whose report the foregoing is condensed, testified as follows as to fertility:

> We grow as fine lemons as you would wish. Along at Florence they have grown splendid olives. In this valley our olive trees are not far enough advanced to tell anything about; but they have grown them up there. We have planted out here some 22,000 orange trees, experiments in growing that have been successful. Peaches, pears, and apples are not so good. They grow to great perfection so far as size is concerned, but they lack flavor. We grow the crab-apple, prunes, and dates. Every variety of figs is a natural product here. The date is produced here seven years from the seed, and in bunches of from 5 to 25 pounds. And we grow wheat here—I should think about 1,800 to 2,000 pounds to the acre. The yield of barley is from 2,000 to 2,500 pounds to the acre, and sometimes as high as 3,000 and 4,000 pounds. Alfalfa is the principal crop. We cut that from three to four times a year, and we cut from 6 to 8 tons to the acre.

The total area of ditch construction and acreage under water is estimated as follows:

County.	No. of canals.	Length.	Area under ditch.
		Miles.	*Acres.*
Apache	....	24½	12,500
Cochise	....	51	8,300
Graham	....	60	35,000
Maricopa	23	304½	194,400
Pima	36	52	30,000
Pinal	28	50	78,000 * 50,000
Yavapai	....	78	40,000
Yuma	10	120½	81,000
Total	....	740½	529,200

* In Pima Reservation.

These figures are entirely taken from county reports. The ditch system constructing in Yuma County will, when completed, have a total length of 241 miles and an acreage of 207,000. The total cost will be $1,318,000, or nearly $5,500 per mile. The canals under way in Maricopa County will, when completed, cover 404,900 acres and have a total length of 425 miles. Apache County reports 150,000 acres reclaimed, Pima County 2,500,000 acres, and Cochise 310,000 acres. Of the area "under ditch" about two-thirds are actually cultivated.

THE FERTILE SALT RIVER VALLEY.

Maricopa County is the central and, agriculturally speaking, the most important section of Arizona. From a report the following statements are quoted:

In the Salt River Valley the following canals have been taken from the Salt River:

Name.	Length.	Name.	Length.
	Miles.		*Miles.*
Arizona	41	Utah	6
Grand	22	Farmers	5
Maricopa	14	Highland	22
Salt River Valley	18	Dutch Ditch	4
San Francisco	9	Monterey	4
Tempe	19	Griffin	3
Mesa	9		

These water-ways cover in the aggregate 250,000 acres of land, of which 187,500 have been reclaimed and 125,000 acres are annually cultivated.

On the Gila are the following canals which have been completed:

Name.	Length.	Acres.	Name.	Length.	Acres.
	Miles.			*Miles.*	
Buckeye	30	20,000	Gould & Bro.'s	8	3,000
Gila River	8	5,000	Palmer	22	12,000
Enterprise	12	6,000	Citrus	14	5,000

Besides which are the following canals now in process of construction: The monarch ditch, 8 miles long, which will cover 2,000 acres; the Gila River Irrigation Company, which takes the water at Black Butte, below the mouth of the Hassayampa River. The company have 12 miles of their canal completed and propose to put in a dam 1,755 feet long and 75 feet high, and carry the water south and southwest, taking in the entire valley on the south and east sides of the river to the line of Yuma County, making a canal 75 miles long and covering 500,000 acres. The Gila Bend Canal Company starts from Gila Bend on the south side of the river. They have completed 22½ miles of the canal, which is to have a total length of 30 miles and cover 18,000 acres. Under this canal about 3,400 acres have been cultivated this season. The same company are building a large canal, taking the water about 2 miles above and running southwesterly a distance of 50 miles, intending to reclaim 80,000 acres, much of which has been filed upon.

Owing to the dryness of the atmosphere, the evaporation is very great in the valleys. During the summer months it will average about four-tenths of an inch every twenty-four hours, so that reservoirs should, wherever possible, be constructed in the higher altitudes.

In the irrigation of lands it is the general policy of our people to flood them in winter, when water is abundant, which, by creating a reservoir of absorption, make frequent and heavy irrigations unnecessary during the months of June and July, when water is scarce. Since the first settlement of the valley of the Salt River the water has risen 30 feet nearer the surface. In some places fruits and alfalfa are grown without irrigation. It seems reasonable to suppose that when the lands on the high mesas along the foot-hill mountains are more generally cultivated the area of land requiring no irrigation will be very largely extended. Another fact is noticeable: The water used in irrigation, except that lost by evaporation, percolates through the soil and finds its way back to the river. More water flows into the Gila from the Salt River in the dry season, covered by the months of May, June, and July, than before the first canal was built in the valley. Forty miner's inches of water is calculated to make a cubic foot flow per second. One miner's foot is sufficient to cultivate 3 acres in grain or alfalfa, and 5 acres in fruits or vineyard.

The principal grain crops of the county are wheat and barley. The past season there has been produced about 40,000,000 pounds of barley and about 30,000,000 pounds of wheat. The yield of wheat is from 1,200 to 1,800 pounds per acre, and of barley from 1,800 to 3,000 pounds per acre. Sorghum and sugar cane are grown to a considerable extent for the sugar they contain and for feed. Corn is not extensively raised, being confined to a few hundred acres each year. Oats are a native of the soil, and are cut in quantities evey year for hay. Timothy, Bermuda, and blue grass do well, but alfalfa is the principal grass grown. Once rooted, it requires no attention except to irrigate it three or four times during the year; grazed, an acre will support two and a half head of horses during the year, and from ten to twelve head of sheep or hogs. It can be cut from four to five times annually. and yields from 6 to 8 tons to the acre The hay is very nutritious, and as a pasture for all kinds of stock can not be surpassed. Three and four year old steers driven from the ranges upon alfalfa pastures gain, if poor, two pounds per day for the first three months, becomming at the end of that time, most excellent beef in any market.

The mesquite and cottonwood are native trees, but the ash, cork elm, pepper tree, catalpa, willow, umbrella, lombardy poplar, North Carolina poplar, mulberry, palm, magnolia, locust, and tamarack have been introduced with marked success.

Up to five years ago very little fruit of any kind was grown in the county, and that only by way of experiment. Since then the planting of orchards and vineyards has increased every year. It has been fully demonstrated that no better section exists for the growing of nearly all citrus and deciduous fruits. In the Lower Gila Valley lemons, oranges, figs, grapes, and pomegranates can be grown in great perfection, but it is not well adapted to the culture of other fruits. In other portions of the valley, and through the valley of the Salt River, peaches, pears, apricots, pomegranates, figs, French prunes, apples, oranges, almonds, quinces, dates, blackberries, and strawberries, and every variety of grapes, grow in perfection.

There are now planted through the Salt River Valley 8,000 acres in vineyard and 3,000 in orchard trees. Of oranges 200 acres are in cultivation; from experiments made the growing of this fruit will be a success. Olives have been planted in an experimental way. It is too soon to speak confidently as to the results, but as they have been successfully cultivated near Florence, in Pinal County, there seems to be no reason to doubt that good results will attend their culture in this county. Apricots, peaches, and kindred fruits bear heavily, yielding from 300 to 500 pounds per tree. Vineyards in full bearing give from 6 to 8 tons to the acre. Raisins have not yet become an export commodity with us, but will be in a short time; the muscat of Alexandria grown in this valley contains a greater quantity of saccharine matter than elsewhere, and from experiments made in raisin making we are justified in the statement that 3 pounds of this grape will make 1 pound of raisins, which is greater than in any part of this habitable globe. Another advantage which our county has in the prosecution of this industry over raisin districts of Spain or California is that the drying and curing can be done in the open air without damage from rain or dew.

Some experiments have been made in the manufacture of sherry wine, with satisfactory results. All our wines have a strong sherry flavor, and expert viticulturists who have examined into the matter claim this to be the only port and sherry district in America. On this subject the Hon. J. De Barth Shorb, commissioner at large of the State Viticulturist Society of California, writes: "I directed what should be done with one barrel of so-called white wine, from the Salt River Valley, as a matter of experiment, and upon examination a few months later, found, as anticipated, it had turned into a sherry of most excellent quality. I have no hesitation in saying that the Phœnix country is the only port and sherry country in America; so far as known, and with trained judgment in the selection of proper varieties of grapes adapted to your conditions, wines of the highest commercial value, if scientific methods be substituted for those now in vogue in the manufacturing of the wines, will be the inevitable result."

The growing of early and late vegetables will also, when railroad facilities are general, be a source of great profit to the people of this country—a country that produces fresh fruits and vegetables every month in the year; where grown in the open air peaches, figs, tomatoes, and cantaloupes can be gathered in December, and where the soil, a rich alluvial, varying in depth from 10 to 12 feet, inexhaustible in its durable fertility, will assuredly be the center of a great and prosperous community. Such are the mesa lands of this county. When reclaimed all vegetation has most rapid development.

The cottonwood and North Carolina poplar grows from 18 to 20 feet in a season, fruit trees from 12 to 15 feet, grape-vines from 25 to 40 feet.

The Indians occupying a reservation in this county have cultivated their land for two hundred years without apparent injury to the soil and without change of seed. After their crude method of farming they raise better crops of grain than are harvested in any of the wheat-growing districts in the Mississippi Valley.

COLORADO AND IRRIGATION.

Colorado is as notable for the physical data it offers in relation to irrigation as it has already been shown to be in the legal aspects thereof. Prof. L. G. Carpenter, of the State agricultural college, reported in January, 1890, the following as the

Approximate areas "under ditch" in Colorado.

	Area.	Total area.	
	Sq. miles.	*Sq. miles.*	*Acres.*
Division I (Platte Division):			
Platte Valley, below the Poudre	283.21		
Platte Valley, above the Poudre, including Bear and Clear Creeks	551.64		
St. Vrain and Boulder Creeks	294.59		
Big and Little Thompson	134.22		
Cache La Poudre	393.54		
Total from South Platte		1,657.20	1,060,608
From North Platte in North Park	....	101.23	64,787
Division II (Arkansas Division):			
East of Huerfano River	480.08		
Cucharas	94.40		
La Veta and Apache	84.17		
Upper Arkansas and Fontaine	106.91		
		774.56	495,718
Division III (Rio Grande Division)	....	1,564.00	1,000,960
Division IV (San Juan Division), including Dolores, Mancos, Pine, Florida, La Plate Rivers	....	135.00	86,400
Division V (Grand River Division)	....	210.00	134,400
Division VI (Bear and White River Division)	....	110.00	70,400
Total	....	4,552.00	2,913,273

By this table the total amount of land under ditch in Colorado at present is not far from 4,500 square miles, or 3,000,000 acres. The amount of land actually irrigated can not be so reliably estimated at present. It is much less than that under ditch.

Professor Carpenter estimates the total irrigated as not over one-third. This is apparently below the actual results. State Engineer Maxwell had presented in September, 1889, the following figures as a careful statement of the area east of the Rocky Mountains:

Divisions.	No. of districts.	Miles of ditches.	Acres.	
			Under ditch.	Actually irrigated.
No. 1 Platte	14	2,067.36	1,126,800	631,036
No. 2 Arkansas	13	943.30	440,240	116,047
No. 3 Rio Grande	8	1,033.68	596,097	250,263
Total	35	4,044.34	2,163,137	997,346

In the three eastern divisions there are also one hundred and sixty-two reservoirs, with a record capacity of 5,319,939,788 cubic feet, capable of furnishing one acre-foot of water to each of 122,199 acres. The total number of ditches, large and small, in the State is estimated at 2,000, and their mileage at 5,000. The duty of water is placed at 1.45 cubic feet per second for 80 acres. In some sections it is over 100 acres, however.

The State engineer, Mr. Maxwell, has reported the following:

> For the distribution, under the irrigation laws of this State, of the water from the natural streams to the irrigating canals, ditches, and reservoirs, the State is divided into six irrigation divisions and sixty-eight water districts.
>
> In a general way, the first division comprises that portion of the State which is drained by the North and South Platte Rivers, the second division of that portion drained by the Arkansas River, and the third division of that portion drained by the Rio Grande.
>
> These three divisions compose the "Eastern Slope," or all that part of the State which drains into the Gulf of Mexico.

EASTERN SLOPE.

Tabulated statement showing the number of miles of irrigating canals and ditches, the number of acres of land under such canals and ditches, and the number of acres of land actually irrigated by such canals and ditches.

[Compiled from data in the State engineer's office.]

SOUTH PLATTE DIVISION, No. 1.

No. of water district.	Name of principal stream in district.	Ditches.	Under ditches.	Actually irrigated.
		Miles.	*Acres.*	*Acres.*
1 6	South Platte	238. 00	150, 000	39, 719

	Total	943. 30	440, 240	116, 047

RIO GRANDE DIVISION, No. 3 (SAN LUIS VALLEY).*

No. of water district.	Name of principal stream in district.	Ditches.	Under ditches.	Actually irrigated.
20	Rio Grande	300. 00	398, 140	98, 515
21	Alamosa	175. 00	57, 711	45, 093
22	Conejos	160. 00	45, 711	33, 340
24	Culebra and Costilla	(†)	(†)	(†)
25	San Luis Creek	227. 78	42, 425	31, 315
26	Saguache	143. 80	33, 380	28, 000
27	La Garita	5. 60	570	500
35	Trinchera	21. 50	18, 160	13, 500
	Total	1, 033. 68	596, 097	250, 263

* The records relating to this division are not complete.

† No data.

RECAPITULATION.

	Ditches.	Under ditches.	Actually irrigated.
Division No. 1	2, 067. 36	1, 126, 800	631, 036
Division No. 2	943. 30	440, 240	116, 047
Division No. 3	1, 033. 63	596, 097	250, 263
Aggregate	4, 044. 29	2, 163, 137	997, 346

Total area of arid land, 30,000,000 acres.

Colorado (eastern slope).—Tabulated summary of reservoirs so far as the same are of record in the office of the State engineer.

DIVISION No. 1.

District.	No. of reservoirs.	Area.	Capacity.
		Acres.	*Cubic feet.*
First	10	....	27,419,536
Second	8	....	538,787,000
Third	5	....	188,994,950
Fourth	1	....	180,000,000
Fifth	2	....	165,164,080
Seventh	21	....	1,114,089,456
Eighth	14	....	1,688,381,817
Ninth	13	....	263,778,940
Twenty-third	1	....	2,214,323
Total	75	....	3,168,780,082

NOTE.—The above number of cubic feet of water would furnish 1 foot in depth for 72,746 acres.

DIVISION No. 2.

Tenth	29	....	115,937,752
Eleventh	3	....	20,613,408
Fourteenth	17	....	1,011,596,143
Sixteenth	8	....	98,329,398
Seventeenth	20	....	823,524,005
Total	77	....	2,069,000,706

NOTE.—The above amount would furnish 1 foot in depth of water for 47,495 acres.

DIVISION No. 3.

Twenty-second	4	....	16,000,000
Twenty-fifth	2	....	66,000,000
Twenty-sixth	1	....	50,000
Twenty-seventh	3	....	109,000
Total	10	....	82,159,000

NOTE.—The above amount would furnish 1 foot in depth for 1,885 acres.

GENERAL RECAPITULATION.

Division.	No. of reservoirs.	Area.	Capacity.
		Acres.	*Cubic feet.*
First	75	....	3,168,720,082
Second	77	....	2,069,000,706
Third	10	....	82,159,000
Grand aggregate	162	....	5,319,939,788

NOTE.—This total amount of water would furnish 1 foot in depth of water for 122,129 acres.

ITS AGRICULTURAL PRODUCTIVENESS.

Colorado is especially adapted to the production of the grains, grasses, and roots of the temperate zone. The eastern foot-hills are found valuable for the fruits thereof, while in the valleys of the western slopes the finer fruits, such as grapes, apricots, etc., can be profitably raised. In the San Juan, to the southwest, the semi-tropical fruits and crops will be cultivated successfully on the mesa and valley lands.

Of the area of Colorado, 98.2 per cent. is not in farms. Of tillable land the area is 23.8 per cent.; grass land, 29; woodland, 3.8; and the unproductive is rated at 43.4 per cent. Colorado stands as to productivity as follows:

	Bushels per acre.	Average.
Corn	27.7	24.2
Wheat	10.6	12.3
Oats	31.7	27.0

From 1884 to 1889, the public domain lying within the borders of Colorado has been occupied to the total of 9,155,561 acres. This is within less than 1,000,000 acres of the total amount of arable land which, in 1880, the public lands commission declared was the whole arable area left for settlement. It is evident that the specialists do not know all the facts or are able to accurately forecast the future.

ONE OF ITS LARGE IRRIGATED AREAS.

In the San Luis Valley there is 468 miles of ditch. One canal, known as the Rio Grande Canal, is the largest in operation at present in the West. There is 312 miles of ditch system. The canal at the head is 80 feet wide on the bottom, and will finally supply water to about 240,000 acres of land. The conditions and character of the soil of the San Luis Valley, on the Rio Grande River, in the southern part of the State, are different from other sections of Colorado. That valley has an area of 5,000 square miles, and probably 3,000,000 acres could be redeemed if the water is there to do it with. Altogether, in the San Luis Valley, there are above it 1,150 or 1,200 miles of canal, supplying about 1,500,000 acres of land. The water supply is not sufficient to irrigate those lands at all times.

The Rio Grande River carries a large amount of flood water during the summer months. There are probably six weeks during the average year when there will be sufficient water to irrigate the entire valley if it could be relied upon. There are fine sites within the mountains adjacent to the valley for building reservoirs.

In order to redeem that entire area it is necessary to conserve the water. With that area 150,000 or 200,000 people can be supported, but with the present irrigating facilities and water supply not more than 50,000 people. The soil is good. The altitude is about 7,500 feet, but the latitude is such that it gives a good locality for irrigation. The San Luis Valley, the largest valley in the Rocky Mountain region, has a soil somewhat peculiar and different from the soil on the eastern slope of the mountains. It is underlaid by a heavy stratum of drift.

Artesian water is found in the San Luis Valley at a depth of 800 feet, a very full flow of water that will cut a figure sometime in the progress of irrigation; but even with such artesian and all the surface water, the valley will not be reclaimed without storage.

Most of San Luis Valley is still public land, but the State has some 200,000 or 250,000 acres therein. In order to induce capital to vinest, the State has passed a law providing for the sale of the State land in alternate quarter sections at $1.25 per acre to any company that would build a canal large enough to supply the entire area. They require the canal company to make a contract and give a bond and supply that land. Capital is not, however, ready to go in and investigate and make the expensive examination necessary to ascertain whether such canals are feasible. There are a number of canal and other irrigating projects, especially in the western and southwestern portions of the State, that would be undertaken if it could be demonstrated they were feasable, but in order to demonstrate that it would require the expenditure of considerable money.

If the information could be got and promulgated, showing that these schemes are feasible, capital might be induced to go in and construct them. That is especially true in Grand Valley. This valley, extending from Grand Junction over to the valley of the Green, in Utah, embraces a fine section of land, but to build a canal that would reclaim the whole of the land that is irrigable therein would require much money. Reconnaissances have been made to ascertain that, and it was ascertained that the canal would cost probably $2,500,000.

THE HISTORY OF GREELEY AND THE FIRST IRRIGATION COLONY.

Union colony is situated in Weld County, State of Colorado. It was located in the spring of 1870, and the town of Greeley was laid out and building and other improvements commenced at the same time. The town is located in sections 5, 6, 7, and 8, township 5 north, range 65 west of the sixth principal meridian; latitude 40° 25′ north, longitude 27° 48′ west from Washington; elevation above sea-level, 4,800 feet. At the time the colony and town were located the whole country was, with few exceptions, in its natural state, no improvements having been made except in a small way along the river. A few small irrigating ditches had been built to water portions of the low bottom-lands, and sufficient farming had been done by the early settlers to demonstrate the fact that good crops of all kinds usually grown in this latitude could be raised successfully.

The mesas or uplands were regarded as worthless for farming purposes, and only valuable for grazing, many of the best informed expressing the opinion that large and long irrigating canals to water the higher lands would be a failure. In support of this view it was said that the water would seep out and be lost before running in a canal any great distance, and that the land would be quickly exhausted if farmed, and various other reasons why upland farming would be liable to prove unsuccessful were pointed out.

Notwithstanding all the uncertainties that must be encountered, the projectors of "The Union Colony of Colorado," located in the Cache la Poudre Valley, purchased the land they required from private owners, and the Denver Pacific Railway Company homesteaded and pre-empted Government land, laid out the town, and proceeded to build irrigating canals to water the same. About 2,600 acres of land was bought of private owners for $28,000, and 9,300 acres of the railway company for $31,000.

The colonists contracted with the railway company for all the land owned by them lying within the colony limits at an average price of $3 per acre. The Government land was acquired by the colonists under the homestead and pre-emption laws. The total amount of land originally occupied by the colony was about 30,000 acres, and remains about the same. Soon after locating the colony built a fence some 40 miles in length, inclosing all their lands, including the town. This fence is still maintained, having been legalized by an act of the State legislature and being managed by a fence company. Each piece or parcel of land pays an annual tax for its maintenance, the annual assessment being about $16 for each 80 acres, and in like proportion for larger or smaller tracts. No stock of any kind is allowed to run at large inside of this fence, and none have found it necessary to fence their premises, either in town or outside, except for their own convenience. The colony originally divided the land owned by them outside of the town limits into lots of 5, 10, 20, and 40 acres each, according to their proximity to town, and deeded them to members, with perpetual right to water from the irrigating canals, for $150 each.

Other members bought land of the railway company for $3 per acre or homesteaded or pre-empted Government land. To these the colony sold right to water in perpetuity for $160 for each 80 acres. All water rights are taxed annually a sufficient amount to pay for superintendence, maintenance, and improvement of the main canals, generally from $12 to $24 annually for each 80 acres and in proportion for smaller subdivisions. Few of the colony farmers have more than 160 acres; generally they have 80, and in some cases as low as 40 or even 20.

The land occupied by the town, some 800 acres, originally cost the colony about $10 per acre, or $8,000. It was subdivided into about fifteen hundred lots of suitable size and sold to members at an average price of about $300 for each ($50 for corner and $25 for inside lots), making about $45,000 as the amount received by the colony for lots. The cash value of such lots was lawfully $300 each, making $450,000. The outside or farming land originally cost members about $5 per acre with water, and is worth $30 per acre cash, with actual sales at $35 and over for land with no improvements except plowing and ditches, including water right, the colony having long since sold all the land and water owned by them and transferred all their right in the main canal used by the farmers to a corporation composed of farmers operating under it. This company issued its stock to the water-right owners on receiving a deed for their interest, each share of stock representing water for 10 acres. In 1878, when this transfer was made, the par value was $40 for each share, making the value of an 80-acre water right $320. In 1881 the price rose to $100 per share, and it now sells at $100 to $125. This stock has actually cost the original owners about its par value, $40 per share. When land is sold including water, the stock is transferred. Nearly all the larger canals are now owned and managed by corporations who have power to levy and compel payments of assessments and divide the water equitably among the users, thus preventing nearly all the trouble which formerly attended the management of the earlier canals. The water costs the farmer the same whether he is situated near the head or at the terminus of the canals, and the same principle has been adopted in the management of the subditches or laterals, as it has been found that no canal from which a number of individuals receive their water can be successfully operated without a competent head.

Union Colony constructed two irrigating canals and one for power and irrigation. The first canal built was for the purpose of supplying the town and adjacent lands lying along the south side of the river. This is called canal No. 3. This canal was taken from the river about 6 miles west of town, and was run on a grade or fall of about 3 feet per mile. Its original size was 8 feet in width at head, and somewhat smaller opposite town. Its length is 10 miles. It terminates on the delta between the Platte and Cache la Poudre Rivers. As originally constructed it would carry about 50 cubic feet of water per second. Original cost about $10,000. It has since been enlarged and improved, its present capacity being over 100 cubic feet per second. Cost to present time, including dam at head, about $25,000.

The second canal built by the colony was taken out the river, about 15 miles west of town, for the purpose of watering the farming lands north of the river. As originally constructed it was 10 feet in width on the bottom at the head and for the first 5 miles, and gradually diminished in size towards its terminus, its total length being 26 miles. Grade or fall, 3.2 feet per mile; capacity, 110 cubic feet per second. It was calculated to water some 20,000 acres of land. Its first cost was $23,000; has been enlarged from time to time, its capacity now being 585 cubic feet per second. It will furnish water for 25,000 acres in cultivation, with the usual variety of crops. Cost to date, $80,000, or about $3 per acre for land watered by it. It is now 25 feet in width on bottom at head, and for the first 10 miles carries water 4.6 feet in depth, and is 30 miles in length. The number of water rights of 80 acres each is 320, giving over 1.8 cubic feet of water per second for each 80 acres, less about 10 per cent. for evaporation and seepage, or about 1.6 cubic feet per second for useful effect. As new land in wheat requires about 1 cubic foot of water for each square foot of surface for first watering, it would take over twenty-five days to water 80 acres with one water right, but generally only a portion of the tract is sown or planted the first year and less water is required after the first thorough irrigation.

Very much depends on the surface quality of soil and subsoil and amount of natural moisture in the ground, so that no very definite information can be given as to the amount of water necessary to irrigate a certain piece of ground. The usual experience is that a cubic foot of water per second waters from 50 to 60 acres of land sown or planted with the usual variety of crops. In town more than double that quantity of water is used, as the more a stream of water is divided up the less ground it will water. The farmers find it to their advantage to use two or three water rights when irrigating a favorable piece of ground by changing with their neighbors. The Cache la Poudre River, from which the colony ditches are taken, generally furnishes enough water when most is needed. There is generally sufficient snow or rain to start crops in the spring and keep wheat and oats growing until the 1st of June.

During June and July the maximum quantity of water is flowing in the river, and it is during these months that most of the crops must be watered. The amount of water flowing in the river each day is ascertained at a gauging station located above all the canals, and the amount or proportion of the water to which each is entitled being known, the district commissioner or superintendent is enabled to divide the water equitably to all. The river or district commissioner is not usually called on unless there is a short supply of water, which usually occurs in the latter portion of the season. The water commissioner on each canal divides the water to each subditch or lateral, and the users divide it among themselves. Since the present State laws regulating the division and distribution of water were enacted and put in force very little trouble has arisen in regard to the use of water for irrigation purposes.

The maximum amount of water flowing in the river each year is very variable, ranging from less than 2,000 to over 6,000 cubic feet per second. As the canals taken from the river have a capacity and use for over 3,000 cubic feet per second, it will readily be seen that there is an element of uncertainty as to water supply and the future extension of the irrigation system. Water has already been appropriated and canals built sufficient to water over 200,000 acres in this valley, and it is not probable that this amount will be very materially increased. The total amount of water flowing in the river during the year would water more than double this quantity of land, but it can only be utilized by a system of storage reservoirs. Comparatively little has as yet been done in the way of storing water in the State, and it is not probable that much will be done for many years to come. Some natural depressions or basins of moderate capacity are used for this purpose where they chance to be available, but no purely artificial reservoirs worth mentioning have as yet been constructed.

The great expense of building and maintaining large reservoirs makes it extremely improbable that our water system will be much extended in this way. Reservoirs to be of any use must be situated above the land to be watered, and where constructed in this vicinity on a small scale the land lying adjacent to them has generally been spoiled by the seepage. The parties owning land which is damaged by such seepage usually compel the owners of the reservoirs to stop using them for storing water. The influence of irrigation on the humidity of the atmosphere is very slight, being almost entirely local, and on new lands, outside of the irrigating canals, farming would be as certain to prove a failure as it would twenty years ago.

If any climatic change ever occurs in this locality whereby the humidity and annual precipitation is permanently increased, it will not be due to the feeble efforts of man. The annual precipitation about Greeley is from 12 to 20 inches, the average being 15 inches for the last twelve years, as observed in Denver. The destruction of the timber in the western mountains must injuriously affect the water supply during the irrigating season by leaving the snow exposed to the direct rays of the sun, causing it to melt quickly and run off. The advance of the farmers from the East with a solid front, plowing up the entire surface, may produce some change. If the annual rain-fall was double what it now is, farming could not be carried on successfully, except in favored localities, the evaporation being so rapid during the growing season. In Greeley, situated on what is called the second bench or bottom, some 25 feet above the level of the river opposite, gardens and lawns must generally be watered every week or ten days in dry weather, and the farmers do not stop irrigating on account of an occasional shower. Much as such increase of natural moisture may be desired, there is no good reasons for expecting it, though there is a reasonable certainty of producing a more equalizing distribution of local rain fall, through the effects of cultivation on the humidity of the soil, and by the influence of wind-breaks and other tree plantations in destroying the desicating effects of the hot winds.

Although this town and surrounding country has been irrigated for many years, raising the ground water, in portions of both town and country, nearly to the surface, causing it to partially fill many of the cellars under dwelling houses, no malarial diseases have been prevalent. The surface soil is generally a clay or sandy loam, from 5 to 10 feet in depth, underlaid with clear sand or coarse gravel 25 to 30 feet in depth, which affords a good natural medium for the rapid transmission of surface water to lower levels, but within the last few years more water has been run on the surface in town than the natural drainage will carry away; and we are now constructing deep drains to prevent the water from rising above a certain level. Said drains are located from 8 to 10 feet below the surface and have a good fall to the river. Our farmers do not keep much stock, as they do now, as formerly, have outside range for them. Alfalfa is grown by nearly all our farmers and yields heavily. It is usually cut three times, giving from 4 to 7 tons per acre annually.

The usual variety of crops is raised, wheat, corn, oats, and potatoes being the principal ones. Wheat is still the main crop, and the quality and yield are generally good. It produces on an average over 25 bushels per acre, when properly put in and attended to. Average of all sown, about 20 bushels. Corn is quite extensively grown, and yields from 20 to 40 bushels per acre; oats about the same, and potatoes from none to 100 bushels per acre, much depending on soil, season, watering at proper time, blight, bugs, etc. In town and vicinity market gardening is successfully carried on. Of fruits, strawberries and raspberries are the ones mostly grown for profit. Standard apples are a failure, but most varieties of crabs do well. It would be difficult to give the aggregate amount and value of all crops raised in this colony without having the report of the State census, taken last year, which is not now available. Nearly all the land in the colony has been farmed continuously for the last ten years, and much of it longer, but its fertility does not seem to decrease.

Crops, when properly rotated, do as well now as when the land was first broken. Scarcely any fertilizers are used on the farming land, and straw is usually burned to get it out of the way. The water used in irrigating the land carries a great amount of fertilizing matter, which is evenly distributed over the surface, fully replacing what is taken from the soil by the crops grown on it; and it is the general opinion of those most conversant with the subject that the soil is practically inexhaustible.

THE IMPORTANCE OF SMALL FARMS.

Thomas P. Dunbar and J. R. Burton, witnesses before the Senate Committee on Irrigaton, stated as to small farms:

> That they produce a better class of crops, fruit, vegetables, hops, and so on. There is a large demand for hops. I know a man making $300 or $400 an acre on hops, and a man can easily make $100 an acre on alfalfa. To get the best results a man must have a small area and cultivate closely and have a supply of farm-yard manure. Our soil here is very heavily charged with mineral matter and is very deficient in manure material. He must grow a variety of crops. We do not want men to raise a large surplus, but we want large communities and to have the land more closely cultivated, so as to bring our population nearer together, and have them produce everything that men can and need to live upon. That is what brings wealth into any State. All our immigration comes from non-irrigated districts. Everything here is new to such immigrants. The conviction is forced on my mind that a man is better off with 40 acres thoroughly cultivated than 160 acres half cultivated. You can not convince the immigrant of it, however.
>
> My observation is that a man is better off with 40 acres in the arid belt with every foot of it well cultivated, and his crop thoroughly attended to, than he is to have 160 acres skimped over. The man with 40 acres in the arid belt, well cultivated, will make more clear money in the end. I will lend him 25 per cent. more money on 40 acres of well cultivated land than on 160 acres half cultivated. The men that have a section of land have to have machinery and all that. Then a man's water-right will go farther on a small farm. His supply of water would have to be all put on at the same time. One great thing is to protect the land from the rays of the sun to prevent baking. You can not do that with a very large farm. I have often gone into an alfalfa field where the alfalfa grows half an inch a day in the warm weather, and within two or three weeks after it had been irrigated the crop was up 6 inches, which would prevent the land from being dried up. I have picked up there as damp a piece of soil as was wanted. On the other hand, I have been in a wet field that had been irrigated a few days before, when there was nothing to protect it from the rays of the sun, and the soil was baked hard.

With regard to the homestead law, I believe a man should not be allowed to preempt more than 40 acres of land in the arid region. I believe the homestead law ought to be amended so that one person could not acquire more than 40 acres of land under its provisions in the arid region. My reasons for this position are, first, the average farmer could make more money farming 40 acres of land by irrigation than he can a larger amount. The homesteader is a poor man, generally. He must borrow the money, at a very high rate of interest, with which to improve his land and live upon it, to provide himself with the necessary farming implements. He must go in debt for water, and wait for the harvest season for any returns from his toil and expenses. If he has 160 acres, his great desire to improve it all causes him to buy too much water, too much farming machinery—in short, it causes him to shoulder too much debt. His taxes and expenses are greater, and he is not capacitated to farm so much land, and farm it well, and the result is his harvest is no greater than it would have been had he carefully cultivated a smaller tract. Instead of getting out of debt and saving a little spare money to invest in live-stock, or to help develop some other industry in his immediate locality, at the end of ten years he is above the average farmer if his quarter section is not mortgaged and a large share of his earnings does not annually go to the money-loaner.

Then, again, it is far better for the ditch company for the farmers to have small holdings of lands. They are enabled to pay out on their water-rights, or to keep up the water-rentals. But a still greater reason is that, if the homesteader could not secure but 40 acres of land, the opportunity for speculators to secure the land in the arid region by engaging professional homesteaders to prove up and obtain title would be greatly lessened. There are localities where ditches or reservoirs could and would be built but for the fact that speculators have obtained the land in this way. The interest of the ditch company and the land-owner ought to be mutual. Where the land is held by farmers for homes, and especially where the land is cultivated, it is so, and there is but little or no friction between the owners of water and the owners of land.

I also think the law ought to be changed, so as to make the cultivation of the land for a given time requisite to obtain title, rather than occupancy. Land that is cultivated in the arid region must have water. If the farm is once put into a state of cultivation and has a water-right attachment there is no danger but that it will be occupied and forever after be a home for somebody. But under the law as it now is a homesteader may put upon the land a trifling building, ever so small and worthless, sleep there occasionally, but in reality live elsewhere, and in a short time have title from the Government, called a homestead, which in reality remains wild land. The spirit of the homestead law is violated, there is no home upon the land; it is used entirely for speculative purposes. I am not stating an exceptional case. In many localities it has been and now is the rule to obtain what is miscalled a homestead in this way.

THE WATER-LAW SYSTEM OF THE STATE.
